Data are shown as standardised β coefficients (p values). $N=771$ to 825. Results are from multiple linear regression models performed separately for each risk factor. Outcome variable is g at year 4. Adjustment of year 4 scores for baseline scores represented four-year change in cognitive performance. Cognitive test scores obtained at year 4 were adjusted for baseline MHVS to estimate the lifetime change in cognitive function. Pack-years are square root transformed. Clinic plasma glucose was transformed to its natural logarithm. MHVS, Mill Hill Vocabulary Scale. Hypertension was defined as systolic blood pressure ≥ 140 mmHg and/or diastolic blood pressure ≥ 85 mmHg and/or self-reported medication prescribed by a doctor to lower blood pressure. Hypercholesterolaemia was defined as plasma total cholesterol ≥ 5 mmol/L and/or self-reported medication prescribed by a doctor to lower blood lipids level. Poor glycaemic control was defined as historical HbA_{1c} $>7\%$ (>53 mmol/mol). Poor blood pressure control was defined as historical systolic blood pressure ≥ 140 mmHg and/or historical diastolic blood pressure ≥ 85 mmHg. Covariates are baseline myocardial infarction, transient ischaemic attack, stroke, angina, duration of diabetes.
