

**S2 Figure. Neutralization of IL-10 during stimulation with *S. aureus*.** Peripheral blood from “patients 1” (n=10) was drawn 24 h (d-1) before and 1 d after injury (d+1). PBMC were stimulated with *S. aureus* in the presence or absence of 10  $\mu\text{g/ml}$  neutralizing monoclonal antibodies against IL-10 ( $\alpha\text{IL-10}$ ). The release of IFN- $\gamma$  into the supernatant was determined by ELISA. Statistical differences were tested using the Friedman test followed by Dunn’s multiple comparison test. \*,  $p < 0.05$
