

Supplemental figure S4. Closing gaps iteratively in a cascading fashion at various values of k in the *E. coli*, *S. cerevisiae*, *C. elegans*, *H. sapiens* and *P. glauca* draft genomes. **A)** Gaps were closed iteratively using a wide range of k -mer values, as described in methods. As a rule of thumb, we start with the largest k -value first in order to more readily resolve repeats, except for *C. elegans* where $k=35$ ran before $k=96$ (peak at 1270). When running iteratively with a range of k -value, the

first k used will typically close the most gaps, except when this value approaches the read length. Bottom right panel: Gap size distribution for gaps closed by Sealer in the human data set at $k=240-40$. **B)** Repeat content analysis in those corresponding *H. sapiens* gap sequences. We ran RepeatMasker (Smit et al., 2013-2015) on gaps that were exclusively closed at the specific k values presented in A), bottom right panel.
