

Figure S3. EV are not stained by gold-conjugated secondary antibodies in the absence of primary anti-Sup35p antibody. EV were fixed with 2% paraformaldehyde, adsorbed onto electron microscopy grids and permeabilized with 0.02% Triton X-100 for 10 min. Electron microscopy grids were incubated with anti-rabbit gold-conjugated antibodies, fixed with 1% glutaraldehyde and then visualized by negative-stain electron microscopy (scale bars: 100 nm).
