1 Examples of Missing Functions

To better understand the pattern of missing functions of a protein, we separately illustrate the BP GO annotations of Human proteins ALG6 and CLDN16 from an old GO annotation (GOA) file to a recent GOA file in Figure S1. In the figure, GO terms in the yellow boxes not circled by blue eclipses are the available GO annotations of the protein by 2010-01-20, and the GO terms in the yellow box circled by blue eclipses are the appended GO annotations of the protein by 2014-06-09. These appended functions are the missing functions of the protein. From the figure, it is easy to find that the missing functions of a partially annotated protein are the descendants of the terms that already associated with the protein.

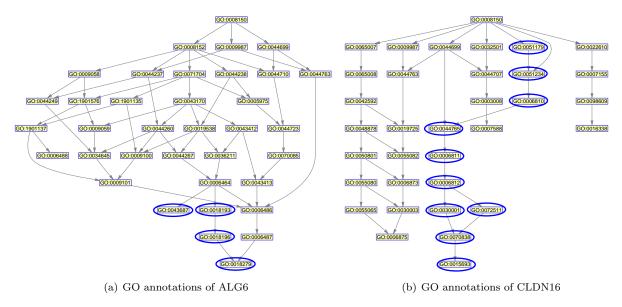

Figure S1: For each sub-figure, the BP GO terms in the yellow boxes are the available GO annotations of the protein by 2010-01-20, and BP GO terms circled by blue eclipses are the appended annotations of the protein by 2014-06-09.

2 Parameter setting and evaluation metrics

2.1 Parameter setting

For the parameter setting of dRW and dRW-kNN, we simply set $\eta = 0.5$ (see Eq. (4) in the main text), which means that a random walker has an equal probability of staying at the start node or to reach its descendant nodes. We optimized the neighborhood size k in $\{1, 2, 3, 4, 5, 10, 20, 30, 40, 50\}$ by five-fold cross validation under the setting of m = 3. We then chose the parameter values that produced the best results. For the experiments on Yeast, we set k = 10, and for the experiments on Human, we set

k=50. ITSS needs to set the neighborhood size k and the threshold value (see Eq. (3) in [1]). The threshold is used to remove pairs of GO terms with low similarity and thus to reduce noise in computing the semantic similarity between proteins. We optimized k in the same range as dRW-kNN and optimized the threshold value from 0 to 1 with step-size 0.1 by five-fold cross validation as for dRW-kNN. For both experiments on Yeast and Human, we set k=50 and the threshold value to 0.9. In the experiments, PILL utilizes the correlation between pairwise function categories to estimate missing functions, without using the protein-protein interactions as in the original paper. In fact, PILL can obtain similar results by directly using the function correlations even without the protein-protein interactions. As the authors reported in [2], we set the threshold value for correlations between functions as 0.05. Naive does not need to set any parameter, since it predicts protein functions simply based on the frequency of functions.

2.2 Evaluation metrics

Here, we give the formal definition of the six evaluation metrics introduced in the main tex: *MacroF1*, *AvgROC*, *RankingLoss*, *Fmax*, *RAccuracy*, and *Coverage*. These metrics are widely used in multi-label learning and protein function prediction [3, 4, 2, 5].

MacroF1 is the average F measure of different GO terms:

$$MacroF1 = \frac{1}{|\mathcal{T}|} \sum_{t \in \mathcal{T}} \frac{2p_t \times r_t}{p_t + r_t}$$

where $|\mathcal{T}|$ is the total number of distinct GO terms (each term corresponds to a label) in \mathcal{T} , p_t and r_t are the precision and recall of the t-th term, defined as:

$$p_t = \frac{TP_t}{TP_t + FP_t}, \quad r_t = \frac{TP_t}{TP_t + FN_t}$$

 TP_t , FP_t , and FN_t are the number of true positive predictions, false positive predictions, and false negative predictions with respect to the t-th term. From the definition, it can be observed MacroF1 first calculates the F measure for each term, and then averages over all the GO terms. MacroF1 is more affected by the performance on sparse terms that associate with fewer proteins, and the missing functions of a protein often correspond to sparse terms. For this reason, we choose MacroF1 as an evaluation metric.

Average ROC (AvgROC) score is a function centric evaluation metric, it averages the receiver operation curve (ROC) score of each function. The ROC score is calculated as the area under the ROC curve, which plots the true positive rate (sensitivity) as a function of the false positive rate (1-specificity) under different classification thresholds. It measures the overall quality of the ranking induced by the classifier, instead of the quality of a single value of the threshold in that ranking.

Ranking loss evaluates the average fraction of GO term pairs that are not correctly ranked:

$$RankingLoss = \frac{1}{N} \sum_{i=l}^{N} \frac{1}{|\mathcal{T}_{i}||\bar{\mathcal{T}}_{i}|} |\{(t_{1}, t_{2}) \in \mathcal{T}_{i} \times \bar{\mathcal{T}}_{i} | \mathcal{L}(i, t_{1}) \leq \mathcal{L}(i, t_{2})\}|$$

where \mathcal{T}_i is the GO annotations of protein i, and $\bar{\mathcal{T}}_i$ is the complement set of \mathcal{T}_i ; $\mathcal{L}(i,t)$ is the predicted likelihood for the i-th protein annotated with the term t. The smaller the value of RankLoss, the better the performance is.

 $\overline{F}max$ is a protein centric evaluation metric suggested in the community-based critical assessment of protein function annotation (CAFA) [4]. Fmax is an F-measure defined as:

$$Fmax = \max_{\tau \in [0,1]} \frac{2p(\tau) \times r(\tau)}{p(\tau) + r(\tau)}$$

where $p(\tau) = \frac{1}{m(\tau)} \sum_{i=1}^{m(\tau)} p_i(\tau)$ is the precision at threshold τ , $p_i(\tau)$ is the precision on the *i*-th protein, $m(\tau)$ is the number of proteins on which at least one prediction was made above the threshold τ , $r(\tau) = \frac{1}{N} \sum_{i=1}^{N} r_i(\tau)$ is the recall across N proteins at threshold τ .

RAccuracy evaluates, overall, how many missing functions of N proteins are correctly replenished:

$$RAccuracy = \frac{1}{N} \sum_{i=1}^{N} \frac{|(\mathcal{T}_i - \hat{\mathcal{T}}_i) \cap \tilde{\mathcal{T}}_i|}{|\mathcal{T}_i - \hat{\mathcal{T}}_i|}$$

where $\hat{\mathcal{T}}_i$ represents the initial functions associated with the *i*-th partially annotated protein, $\tilde{\mathcal{T}}_i$ represents the predicted missing functions, $(\mathcal{T}_i - \hat{\mathcal{T}}_i)$ corresponds to the missing functions, and $(\mathcal{T}_i - \hat{\mathcal{T}}_i) \cap \tilde{\mathcal{T}}_i$ contains the correctly predicted missing functions for this protein.

Coverage evaluates how far, on average, we need to go down the GO terms ranking list to cover all the ground-truth annotations of the protein:

$$Coverage = \frac{1}{N} \sum_{i=1}^{N} \max_{t \in \mathcal{T}_i} rank(\mathcal{L}(i, t)) - 1$$

where $rank(\mathcal{L}(i,\cdot))$ is a rank function, which ranks the largest $\mathcal{L}(i,\cdot) \in R^{|\mathcal{T}|}$ as 1 and the smallest $\mathcal{L}(i,\cdot)$ as $|\mathcal{T}|$. Coverage is often bigger than 1. Obviously, the smaller the value of Coverage is, the better the performance is.

To keep consistency with other evaluation metrics, we report 1-RankLoss instead of RankLoss. Thus, the higher the value of these evaluation metrics (except Coverage), the better the performance is. MacroF1 and RAccuracy require the predicted likelihood score vector $\mathcal{L}(i,\cdot)$ to be a binary indicator vector. We consider the functions corresponding to the q largest values of $\mathcal{L}(i,\cdot)$ as the functions of the i-th protein. In the experiments, $q = |\mathcal{T}_i|$.

3 Missing function prediction

In the main text, we reported the results on the Yeast annotated with BP functions. Here, the results on Yeast and Human annotated with functions in other sub-ontologies are provided in Tables S1-S5. The results of the AUC difference between dRW-kNN and ITSS on different groups of GO terms on Yeast and Human are reported in Figures S2-S6. Obviously, these results lead to similar observations and conclusions as in the main text.

Table S1: Results of predicting the missing CC functions of partially annotated Yeast proteins $(N=5914, |\mathcal{T}|=731)$. The numbers in **boldface** denote the best (or comparable best) statistically significant performance (according to a t-test at 95% significance level). \downarrow means the lower the value, the better the performance. m is the number of missing functions for a protein, N_m is the total number of missing functions and $|\mathcal{T}_m^0|$ is the number of the second kind of missing functions of N proteins for a given m. $m=1, |\mathcal{T}_1^0|=51, N_1=4107; m=3, |\mathcal{T}_3^0|=150, N_3=12293; m=5, |\mathcal{T}_5^0|=238, N_5=20141.$

4 The Influence of Semantic Similarity

The experimental results of dRW, dRW-Corpus, dRW-Disjoint and dRW-E on Yeast and Human are provided in Tables S6-S10. dRW-Corpus performs downward random walks with restart on the GO hierarchy based on the Lin's corpus similarity [6]. dRW-Disjoint does downward random walks with restart based on the recently proposed disjoint axioms similarity [7]. dRW-E assumes the downward transition probabilities from a GO term to its children GO terms are all equal, and then applies dRW on the GO hierarchy. These data also provide similar observations and conclusions as given in the main text.

Table S2: Results of predicting the missing MF functions of partially annotated Yeast proteins ($N=5914, |\mathcal{T}|=546$). The numbers in **boldface** denote the best (or comparable best) statistically significant performance (according to a t-test at 95% significance level). \downarrow means the lower the value, the better the performance. m is the number of missing functions for a protein, N_m is the total number of missing functions and $|\mathcal{T}_m^0|$ is the number of the second kind of missing functions of N proteins for a given m. $m=1, |\mathcal{T}_1^0|=71, N_1=4304; m=3, |\mathcal{T}_3^0|=246, N_3=11362; m=5, |\mathcal{T}_5^0|=386, N_5=16829.$

Table S5: Results of predicting the missing MF functions of partially annotated Human proteins $(N=5914, |\mathcal{T}|=1772)$. The numbers in **boldface** denote the best (or comparable best) statistically significant performance (according to a t-test at 95% significance level). \downarrow means the lower the value, the better the performance. m is the number of missing functions for a protein, N_m is the total number of missing functions and $|\mathcal{T}_m^0|$ is the number of the second kind of missing functions of N proteins for a given m. $m=1, |\mathcal{T}_1^0|=50, N_1=11104; m=3, |\mathcal{T}_3^0|=234, N_3=28533; m=5, |\mathcal{T}_5^0|=421, N_5=43297.$
