

Supplemental Information

Supplemental Methods

Mice. Mice bearing a conditional floxed *Dnmt3a* allele were crossed to mice carrying *LSL Nras*^{G12D/+} or *Mx1-Cre* to generate *LSL Nras*^{G12D/+}; *Dnmt3a*^{fl/+} and *Dnmt3a*^{fl/+}; *Mx1-Cre* mice, respectively. These two compound mice were further crossed to generate the experimental mice, including *LSL Nras*^{G12D/+}; *Dnmt3a*^{fl/+}; *Mx1-Cre*, *LSL Nras*^{G12D/+}; *Mx1-Cre* and *Mx1-Cre* mice. These lines were maintained in a pure C57BL/6 genetic background (>N10).

Genotyping of leukemia cells. Genomic DNAs were extracted from bone marrow, spleen, liver, and thymus of diseased recipient mice using Gentra Puregene Cell Kit (QIAGEN). Genotyping of the floxed or recombined *Kras*^{G12D} and *Dnmt3a* alleles was performed as previously described (1, 2).

Colony forming analysis. The methylcellulose based medium M3234 and M3434 were obtained from StemCell Technologies. To detect erythroid burst-forming unit (BFU-E) and other types of colonies (CFU-G, CFU-M, CFU-GM and CFU-GEMM), 2×10^4 bone marrow cells (from all groups of animals) and 2×10^5 (from *Kras*^{G12D/+} and *Kras*^{G12D/+}; *Dnmt3a*^{-/-} mice) or 1×10^6 spleen cells (from control and *Dnmt3a*^{-/-} mice) were plated in duplicate in semisolid methylcellulose (M3434) according to the manufacturer's protocol. Colonies were counted after 7 days in culture. For replating analysis, 2×10^4 bone marrow cells isolated from various groups of mice were plated in duplicate in M3234 containing 1 ng/ml of IL-3. Colonies were counted after 7 days in culture and same numbers of cells were re-plated.

To detect CFU-E colonies, 2×10^5 bone marrow and 1×10^6 spleen cells from control mice and 2×10^5 bone marrow and 7.5×10^5 spleen cells from *D3a*^{-/-} mice were plated in duplicate in M3234 in the absence or presence of various concentrations of EPO (StemCell Technologies) according to the manufacturer's protocol. Colonies were counted after 2 days in culture.

Bone marrow transplantation. Bone marrow cells were isolated from various compound mice. 2.5×10^5 bone marrow cells (CD45.2⁺) along with same number of competitor cells (CD45.1⁺) were injected into lethally irradiated CD45.1⁺ recipients as previously described (3). Four weeks after transplantation, Cre expression was induced as described above. Peripheral blood was collected regularly to monitor the development of hematopoietic malignancies.

Complete blood count (CBC) and histopathology. CBC analysis was performed using a Hemavet 950FS (Drew Scientific). Mouse tissues were fixed in 10% neutral buffered formalin (Sigma-Aldrich) and further processed at the Histology Lab of the University of Wisconsin Carbone Cancer Center.

Supplemental Figure Legends

Figure S1. Loss of *Dnmt3a* induces a transient anemia *in vivo*. Control and *Dnmt3a^{fl/fl}; Mx1-Cre* mice were treated with pI-pC as described in Materials and Methods. (A) Complete blood count was performed regularly after pI-pC treatment. The results are presented as means \pm SD. ***P<0.001. (B) Different lineages of cells from bone marrow (BM), spleen (SP), and peripheral blood (PB) of control and *Dnmt3a^{-/-}* mice were analyzed using flow cytometry two months after pI-pC treatment. No significant changes were observed.

Figure S2. Loss of *Dnmt3a* induces moderately increased erythropoiesis in spleen two months after pI-pC treatment. Control and *Dnmt3a^{fl/fl}; Mx1-Cre* mice were treated with pI-pC and sacrificed two months after pI-pC treatment when *Dnmt3a^{-/-} (D3a^{-/-})* mice developed a transient anemia. (A) Representative spleen histologic H&E sections from control and *D3a^{-/-}* mice. (B, C) Erythroid differentiation was analyzed in bone marrow (BM) and spleen (SP) of control and *D3a^{-/-}* mice as previously described (4). (E,F) CFU-E assay was performed in the absence or presence of various concentrations of EPO. Colony numbers cultured in the presence of 3 U/ml of EPO are shown (E) and set as 100% (F). The results are presented as means \pm SD. * P<0.05.

Figure S3. Recipients transplanted with *Dnmt3a^{-/-}* bone marrow cells die of hematopoietic malignancies after a prolonged latency. 2.5×10^5 control or *Dnmt3a^{-/-}* bone marrow cells along with same number of competitor cells were transplanted into individual lethally irradiated mice. (A) Kaplan-Meier survival curves were plotted against days after transplantation. (B) Quantification of thymus and spleen weights in different groups of recipients. (C) Flow cytometric analysis of lymphoid compartment in different hematopoietic tissues. The results are presented as means \pm SD. * P<0.05.

Figure S4. Representative spleen histologic H&E sections from moribund recipient mice transplanted with *Kras*^{G12D/+} (Kras) or *Kras*^{G12D/+}; *Dnmt3a*^{-/-} (Kras; D3a^{-/-}) cells. MPN, myeloproliferative neoplasm; AML, acute myeloid leukemia.

Figure S5. Genotyping analysis of leukemia cells. Bone marrow cells from moribund recipient mice with myeloid diseases were isolated. Genomic DNAs from various mice were subjected to genotyping analysis as described in Supplemental methods.

Figure S6. Loss of *Dnmt3a* in *Kras*^{G12D/+} cells promotes development of two types of T-ALL. Lethally irradiated mice were transplanted with 2.5×10^5 bone marrow cells from different groups of mice along with same number of competitor cells. Four weeks after transplantation, Cre expression was induced by pI-pC injections. (A) Frequency of donor-derived T cells (Thy1.2⁺ CD19⁻) in thymus from different groups of recipients. (B, C) Quantification of CD4⁻ CD8⁻ T cells in thymus (B) and thymus weight (C). (D) Analysis of *Notch1* type I deletion in different groups of recipient mice with T-ALL. The results are presented as means \pm SD. * P<0.05, ** P<0.01 and *** P<0.001.
