

Cox regression models showing the predictive performance of the Heng score combined with GNRI and/or MNA-SF scores. The predictive performance is represented by the model's likelihood ratio χ^2 and adequacy index (% likelihood ratio χ^2 attributable to the nested model). *P* values shown are of an LR χ^2 test for nested models.

Annotation: The maximum predictive performance was achieved by combining all scores. Each model was then compared with the maximum model. A model with a higher adequacy index provided better performance. Statistical comparisons were performed using the likelihood test, which was more sensitive.
