

**Online-only Supplementary Data**

Sex-age-specific association of body mass index with all-cause mortality among 12.8 million  
Korean adults : a prospective cohort study

BMI, body mass index; NHIS, National Health Insurance Service of Korea; SD, standard deviation

<sup>a</sup> Participants self-reported pre-existing illness either cured or not through questionnaire at enrollment.<sup>b</sup> Those excluding the first 5-year of deaths<sup>c</sup> Participants self-reported smoking status and known pre-existing illness either cured or not (including cardiovascular disease, cancer, liver disease, diabetes, a respiratory disease, or other diseases) through questionnaire.

**Table S2. Death rate<sup>a</sup> and hazard ratio<sup>b</sup> of death associated with body mass index according to sex and age<sup>c</sup> among all participants (n=12,832,637).**

| Table S2               |                              | Men (n=7,300,575)      |               |                         |          |                   | Women (n=5,532,062)    |               |                         |          |                   |

BMI, body mass index; CI, confidence interval; HR, hazard ratio.

<sup>a</sup> Uniformly age-standardized death rate per 100,000 person-years (namely, the simple mean of calculable age-specific rates in the 14 age-specific rates at ages 18-24 years, 25-29 years, and up to 85 years or older, increasing by 5 years per group, based on age attained during follow-up) was calculated for each BMI category. Several age-specific rates were calculated at each age group. The age-specific rate in the oldest ages at each age group can be very high due to small number of follow-up years. Therefore, death rate at a BMI category can be very high compared to other categories.

<sup>b</sup> Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at enrollment (continuous variable), smoking status (current smoker, former smoker, never-smoker, and those with missing smoking status), and known pre-existing illness either cured or not (yes, and no including those with missing information).

<sup>c</sup> Age groups at 18-34 years, 35-44 years, 45-54 years, 55-64 years, 45-64 years, 65-74 years, and 75-99 years as well as 45-49 years and 50-64 years (only in women).

<sup>d</sup> 18 categories.

**Table S3. Apparent optimal<sup>a</sup> and acceptable<sup>a</sup> ranges of body mass index<sup>b</sup> for longevity in never-smokers.**

| Age (years) | Men           |              | Women       |                        |                        |
|-------------|---------------|--------------|-------------|------------------------|------------------------|
|             | Optimal range | Normal range | Age (years) | Optimal range          | Normal range           |
| 18-34       | 22.0-25.9     | 20.0-27.9    | 18-34       | 15.5-24.9 <sup>c</sup> | 15.5-24.9 <sup>c</sup> |
| 35-44       | 23.0-25.9     | 22.0-27.9    | 35-44       | 19.0-23.9              | 17.5-25.9              |
| 45-54       | 24.0-26.9     | 23.0-27.9    | 45-49       | 20.0-25.9              | 19.0-26.9              |
|             |               |              | 50-54       | 22.0-27.9              | 21.0-28.9              |
| 55-64       | 24.0-27.9     | 23.0-31.4    | 55-64       | 23.0-27.9              | 22.0-29.9              |
| 65-74       | 25.0-28.9     | 23.0-31.4    | 65-74       | 24.0-28.9              | 22.0-31.4              |
| 75-99       | 25.0-34.9     | 24.0-34.9    | 75-99       | 24.0-29.9              | 22.0-36.4 <sup>d</sup> |

<sup>a</sup> Generally, the ranges with an excess risk below 5%, relative to the lowest potential risk (the lowest unweighted geometric mean of hazard ratios at three consecutive body-mass index categories), were considered the optimal ranges, while the ranges with an excess risk below 15%, relative to the potential lowest risk, were deemed the acceptable ranges for each sex-age group. For example, in lifetime non-smoking men aged 18-34 years, the potential lowest risk were 0.91 (the geometric mean of hazard ratios at BMI of 23-23.9 [hazard ratio=0.95], 24-24.9 [0.92], and 25-25.9 [0.86]; Figure S5). The relative hazard at 26-26.9 kg/m<sup>2</sup> (hazard ratio=1.0) was 1.10 (1.0/0.91), and the excess risk was 10%. Thus, in lifetime non-smoking men aged 18-34 years, BMI of 26-26.9 kg/m<sup>2</sup> was considered the acceptable range.

<sup>b</sup> Body mass index (weight in kilograms divided by the square of the height in meters; kg/m<sup>2</sup>). Weight and height were measured while examinees wore light clothing without shoes.

<sup>c</sup> The lower end (15.5) of the range is the median of body mass index in the lowest body mass index category (<16) among all participants.

<sup>d</sup> The higher end (36.4) of the range is the median of body mass index in the highest body mass index category (35.0-50.0) among all participants.

**Table S4. Death rate<sup>a</sup> and hazard ratio<sup>b</sup> of death associated with 11 categories<sup>c</sup> of body mass index according to smoking status and age<sup>d</sup> in men among all participants (n=7,300,575).**

| Men                    |                              | Never-smokers (n=2,523,287) |               |                         |          |                   | Current smokers (n=3,483,108) |               |                         |          |                   | Former smokers (n=1,017,048) |               |                         |          |                   |

BMI, body mass index; CI, confidence interval; HR, hazard ratio.

<sup>a</sup> Uniformly age-standardized death rate per 100,000 person-years (namely, the simple mean of calculable age-specific rates in the 14 age-specific rates at ages 18-24 years, 25-29 years, and up to 85 years or older, increasing by 5 years per group, based on age attained during follow-up) was calculated for each BMI category. Several age-specific rates were calculated at each age group. The age-specific rate in the oldest ages at each age group can be very high due to small number of follow-up years. Therefore, death rate at a BMI category can be very high compared to other categories.

<sup>b</sup> Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at enrollment (continuous variable), smoking status (current smoker, former smoker, never-smoker, and those with missing smoking status), and known pre-existing illness either cured or not (yes, and no including those with missing information).

<sup>c</sup> Due to relatively small numbers in some subgroups, analysis of 11 categories produced more stable results than analysis of 18 categories.

<sup>d</sup> Age groups at 18-44 years, 45-64 years, and 65-99 years.

<sup>e</sup> 11 categories.

**Table S5. Death rate<sup>a</sup> and hazard ratio<sup>b</sup> of death associated with seven categories<sup>c</sup> of body mass index according to smoking status and age<sup>d</sup> in women among all participants (n=5,532,062).**

| Women                  |                              | Never-smokers (n=4,913,461) |               |                         |          |                   | Current smokers (n=174,358) |               |                         |          |                   | Former smokers (n=83,602) |               |                         |          |                   |

BMI, body mass index; CI, confidence interval; HR, hazard ratio.

<sup>a</sup> Uniformly age-standardized death rate per 100,000 person-years (namely, the simple mean of calculable age-specific rates in the 14 age-specific rates at ages 18-24 years, 25-29 years, and up to 85 years or older, increasing by 5 years per group, based on age attained during follow-up) was calculated for each BMI category. Several age-specific rates were calculated at each age group. The age-specific rate in the oldest ages at each age group can be very high due to small number of follow-up years. Therefore, death rate at a BMI category can be very high compared to other categories.

<sup>b</sup> Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at enrollment (continuous variable), and known pre-existing illness either cured or not (yes, and no including those with missing information).

<sup>c</sup> Due to relatively small numbers in some subgroups, analysis of 7 categories produced more stable results than analysis of 18 categories.

<sup>d</sup> Age groups at 18-44 years, 45-64 years, and 65-99 years

<sup>e</sup> 7 categories.

**Table S6. Hazard ratio<sup>a</sup> of death associated with standard five categories<sup>b</sup> of body mass index according to sex and age<sup>c</sup> (6 groups) among all participants and never-smokers.**

BMI, body mass index; CI, confidence interval; HR, hazard ratio.

<sup>a</sup> Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at enrollment (continuous variable), sex(men, and women; only in the analysis for both sexes combined) smoking status (current smoker, former smoker, never-smoker, and those with missing smoking status; only in the analysis for all participants), and known pre-existing illness either cured or not (yes, and no including those with missing information).

<sup>b</sup> 5 categories. Analysis was done for comparison with other research using current standard cut-off points.

<sup>c</sup> Age groups at all ages, 18-34 years, 35-44 years, 45-54 years, 55-64 years, 45-64 years, 65-74 years, and 75-99 years.

**Table S7. Hazard ratio<sup>a</sup> of death associated with standard four categories<sup>b</sup> of body mass index according to sex and age<sup>c</sup> (6 groups) among all participants and never-smokers.**

BMI, body mass index; CI, confidence interval; HR, hazard ratio.

<sup>a</sup> Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at enrollment (continuous variable), sex(men, and women; only in the analysis for both sexes combined) smoking status (current smoker, former smoker, never-smoker, and those with missing smoking status; only in the analysis for all participants), and known pre-existing illness either cured or not (yes, and no including those with missing information).

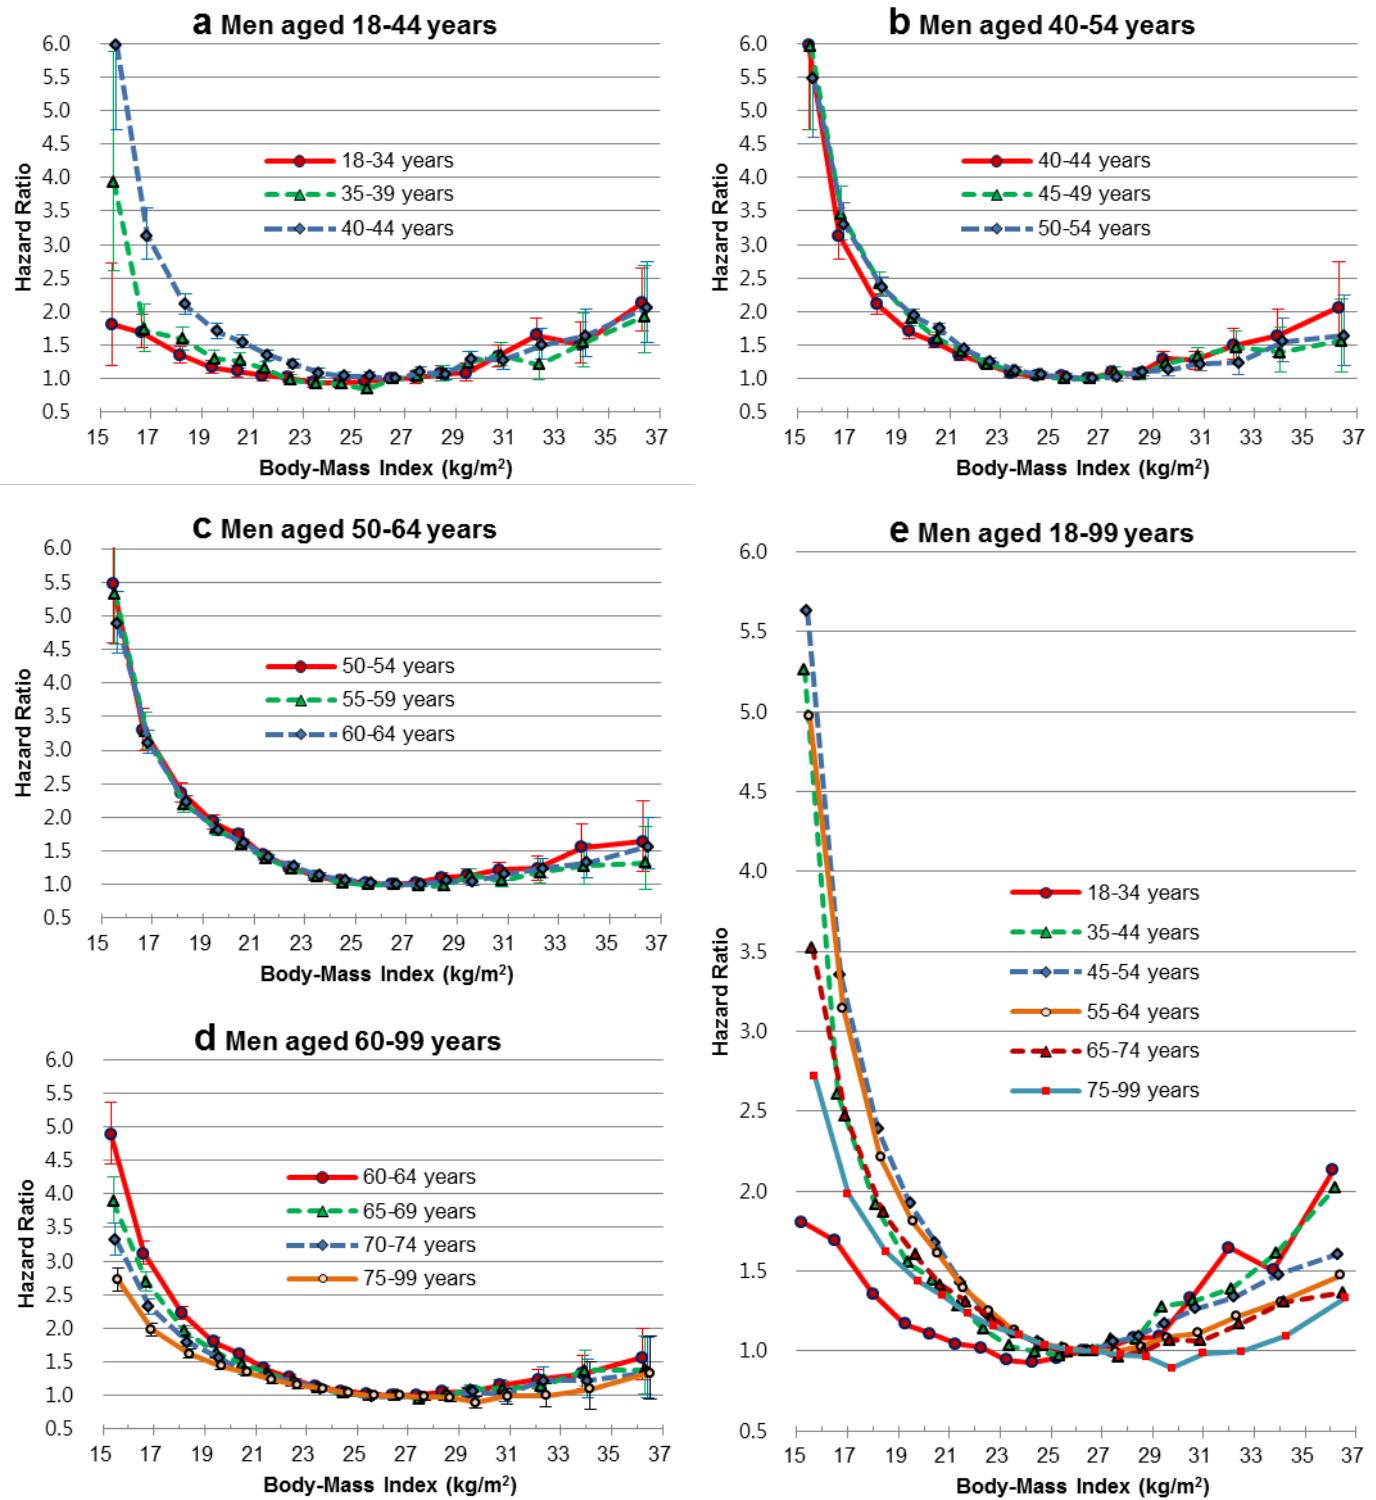

<sup>b</sup> 4 categories. Analysis was done for comparison with other research using current standard cut-off points.

<sup>c</sup> Age groups at all ages, 18-34 years, 35-44 years, 45-54 years, 55-64 years, 45-64 years, 65-74 years, and 75-99 years.

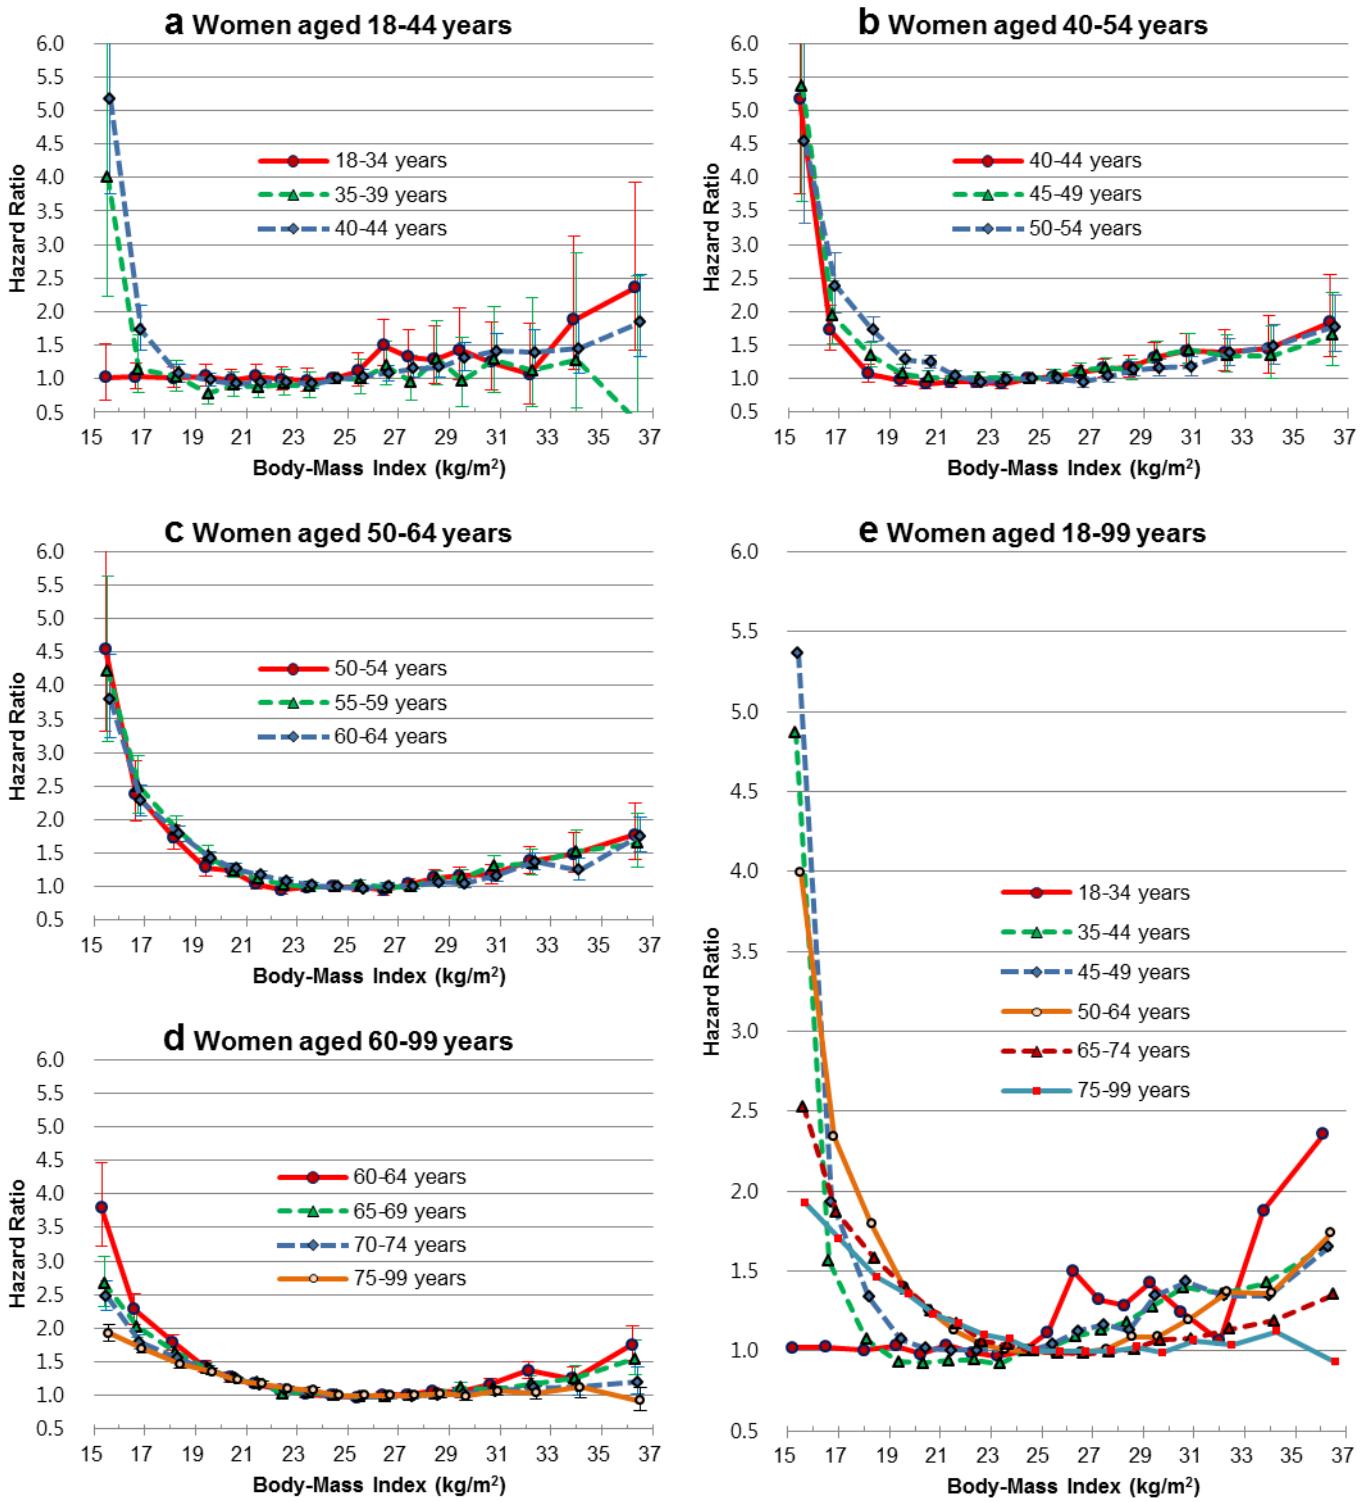

**Figure S1. Hazard ratios of risk of death associated with body-mass index according to subgroup in all participants and never-smokers.**

Hazard ratios were calculated using Cox proportional hazard models. 18 categories of body-mass index (reference: 26.0-26.9 for men and 24.0-24.9 for women) were used. The midpoint was used as a representative value for each body-mass index category, except for both ends (15.5 and 36.4), for which the median of all participants was used. The analyses were adjusted for age, smoking status (except non-smokers), and known pre-existing illness (except people with no known previous illness).

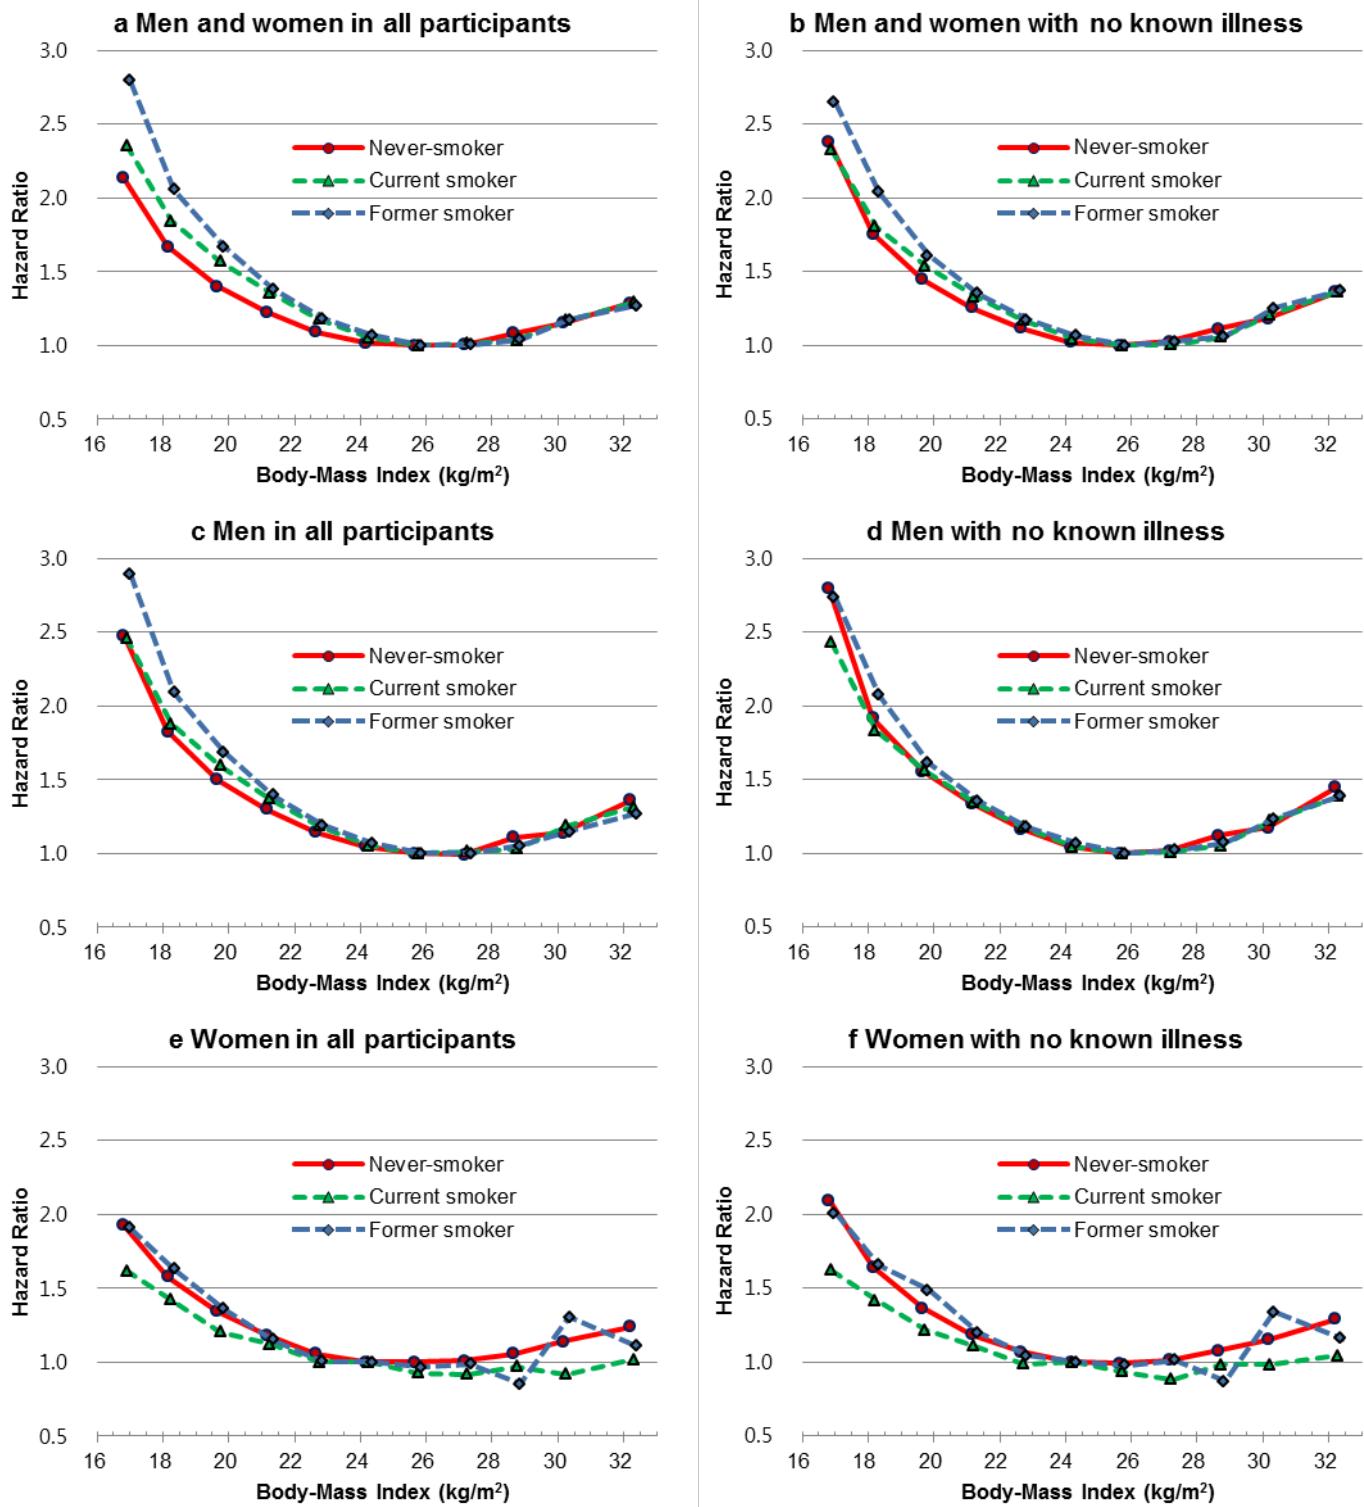

**Figure S2. Age-specific hazard ratios of risk of death associated with body-mass index in men.**

Hazard ratios and 95% confidence intervals were calculated using Cox proportional hazard models. 18 categories of body-mass index (reference: 26.0-26.9) were used. The midpoint was used as a representative value of each body-mass index category, except for both ends (15.5 and 36.4), for which the median of all participants was used. The analyses were adjusted for age, smoking status, and known pre-existing illness.

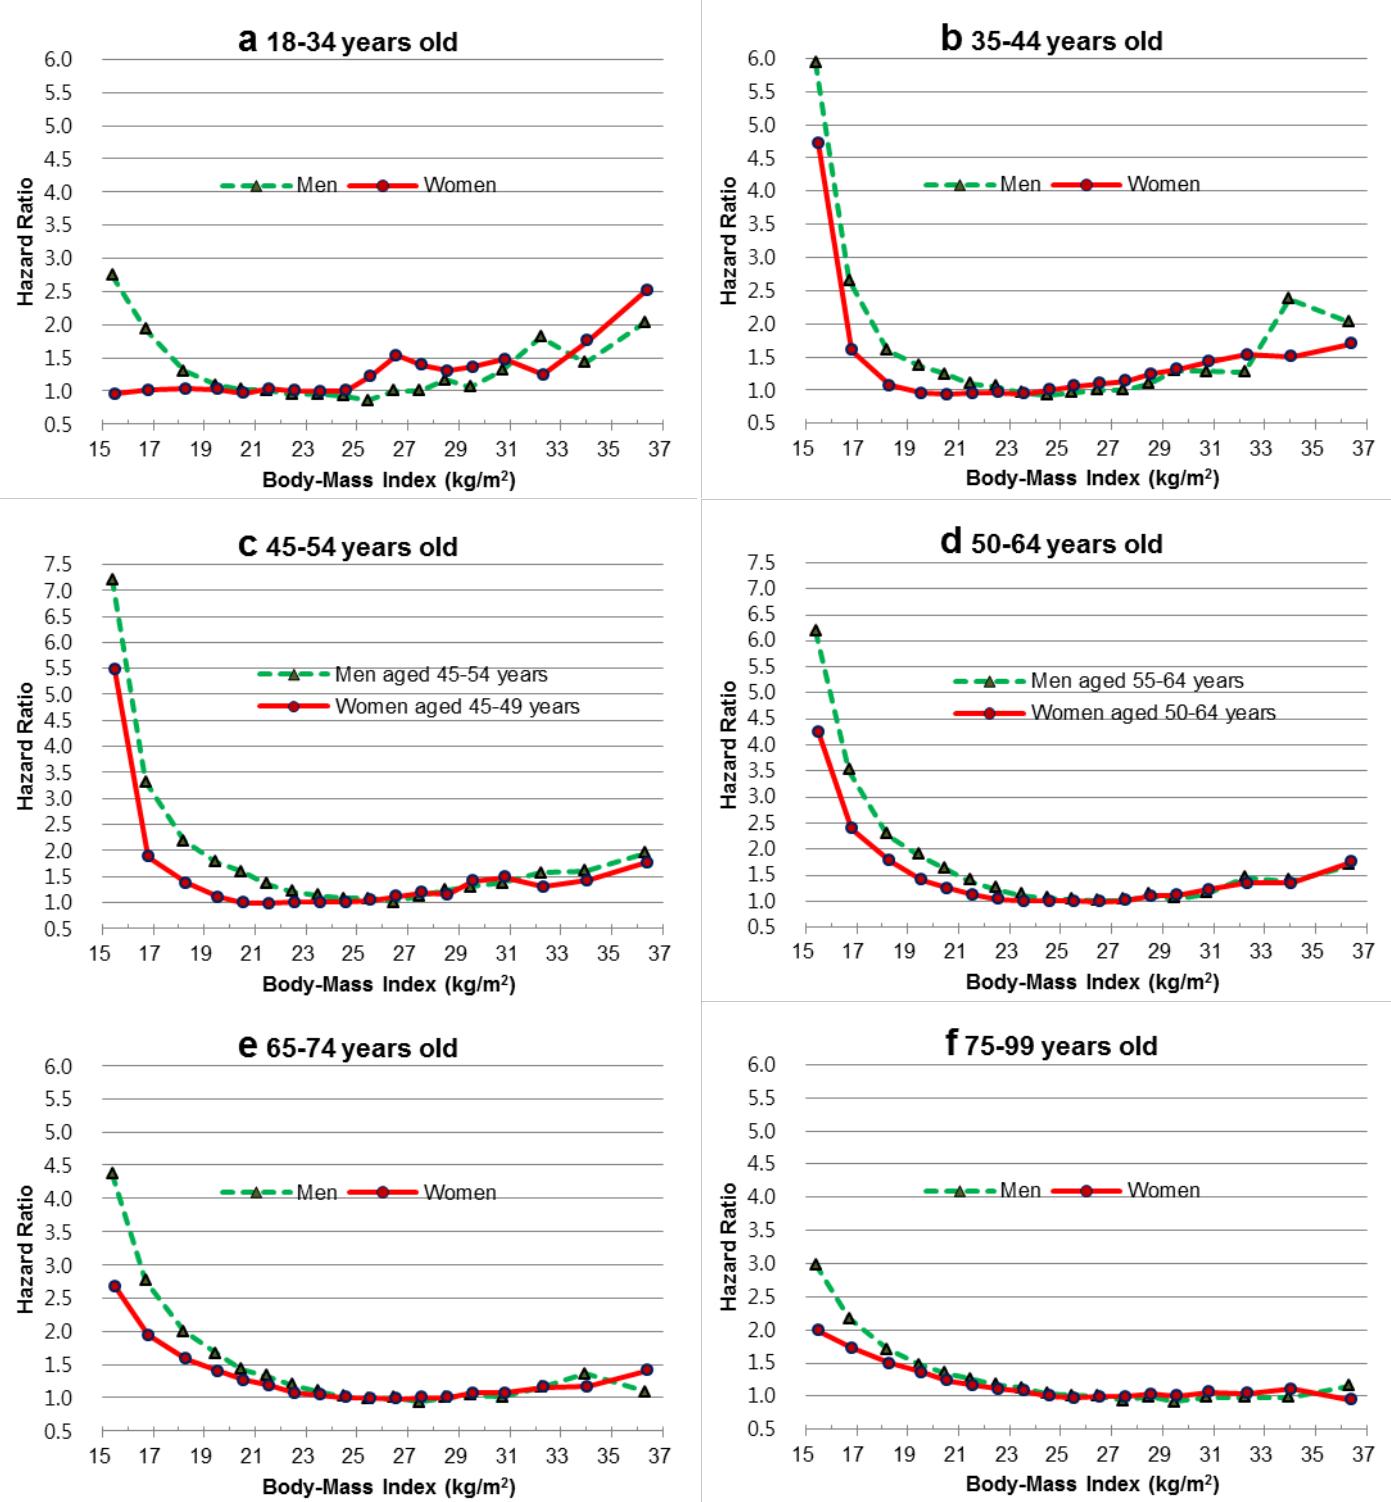

**Figure S3. Age-specific hazard ratios of risk of death associated with body-mass index in women.**

Hazard ratios and 95% confidence intervals were calculated using Cox proportional hazard models. 18 categories of body-mass index (reference: 24.0-24.9) were used. The midpoint was used as a representative value of each body-mass index category, except for both ends (15.5 and 36.4), for which the median of all participants was used. The analyses were adjusted for age, smoking status, and known pre-existing illness.

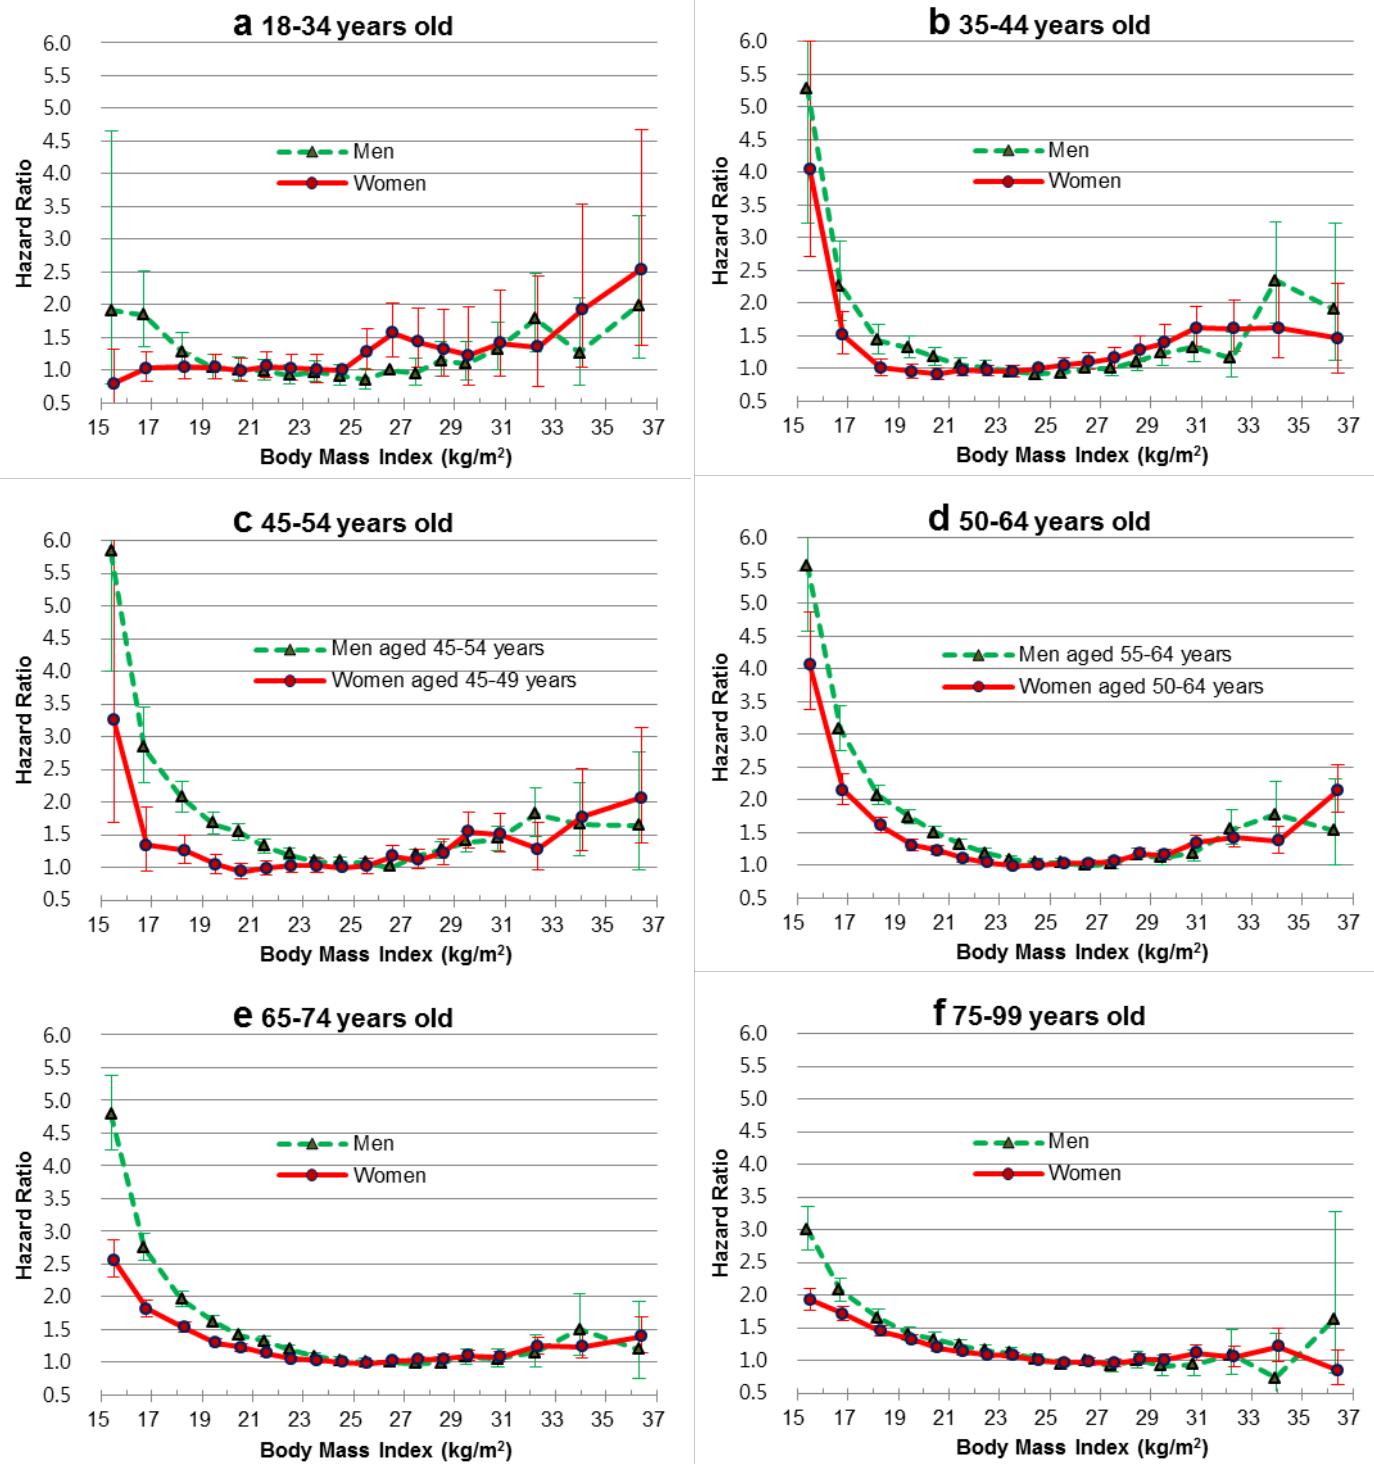

**Figure S4. Hazard ratios of risk of death associated with body-mass index according to smoking status and sex in all participants and those with no known illness.**

Hazard ratios were calculated using Cox proportional hazard models. 11 categories of body-mass index were used (reference: 25.0-26.5 for men and two sexes combined and 23.5-25.0 for women). The midpoint was used as a representative value of each body-mass index category, except for both ends (16.9 and 32.3), for which the median of all participants was used. The analyses were adjusted for age, sex (men, and women; only in the analysis for both sexes combined), and known pre-existing illness (only for all participants).

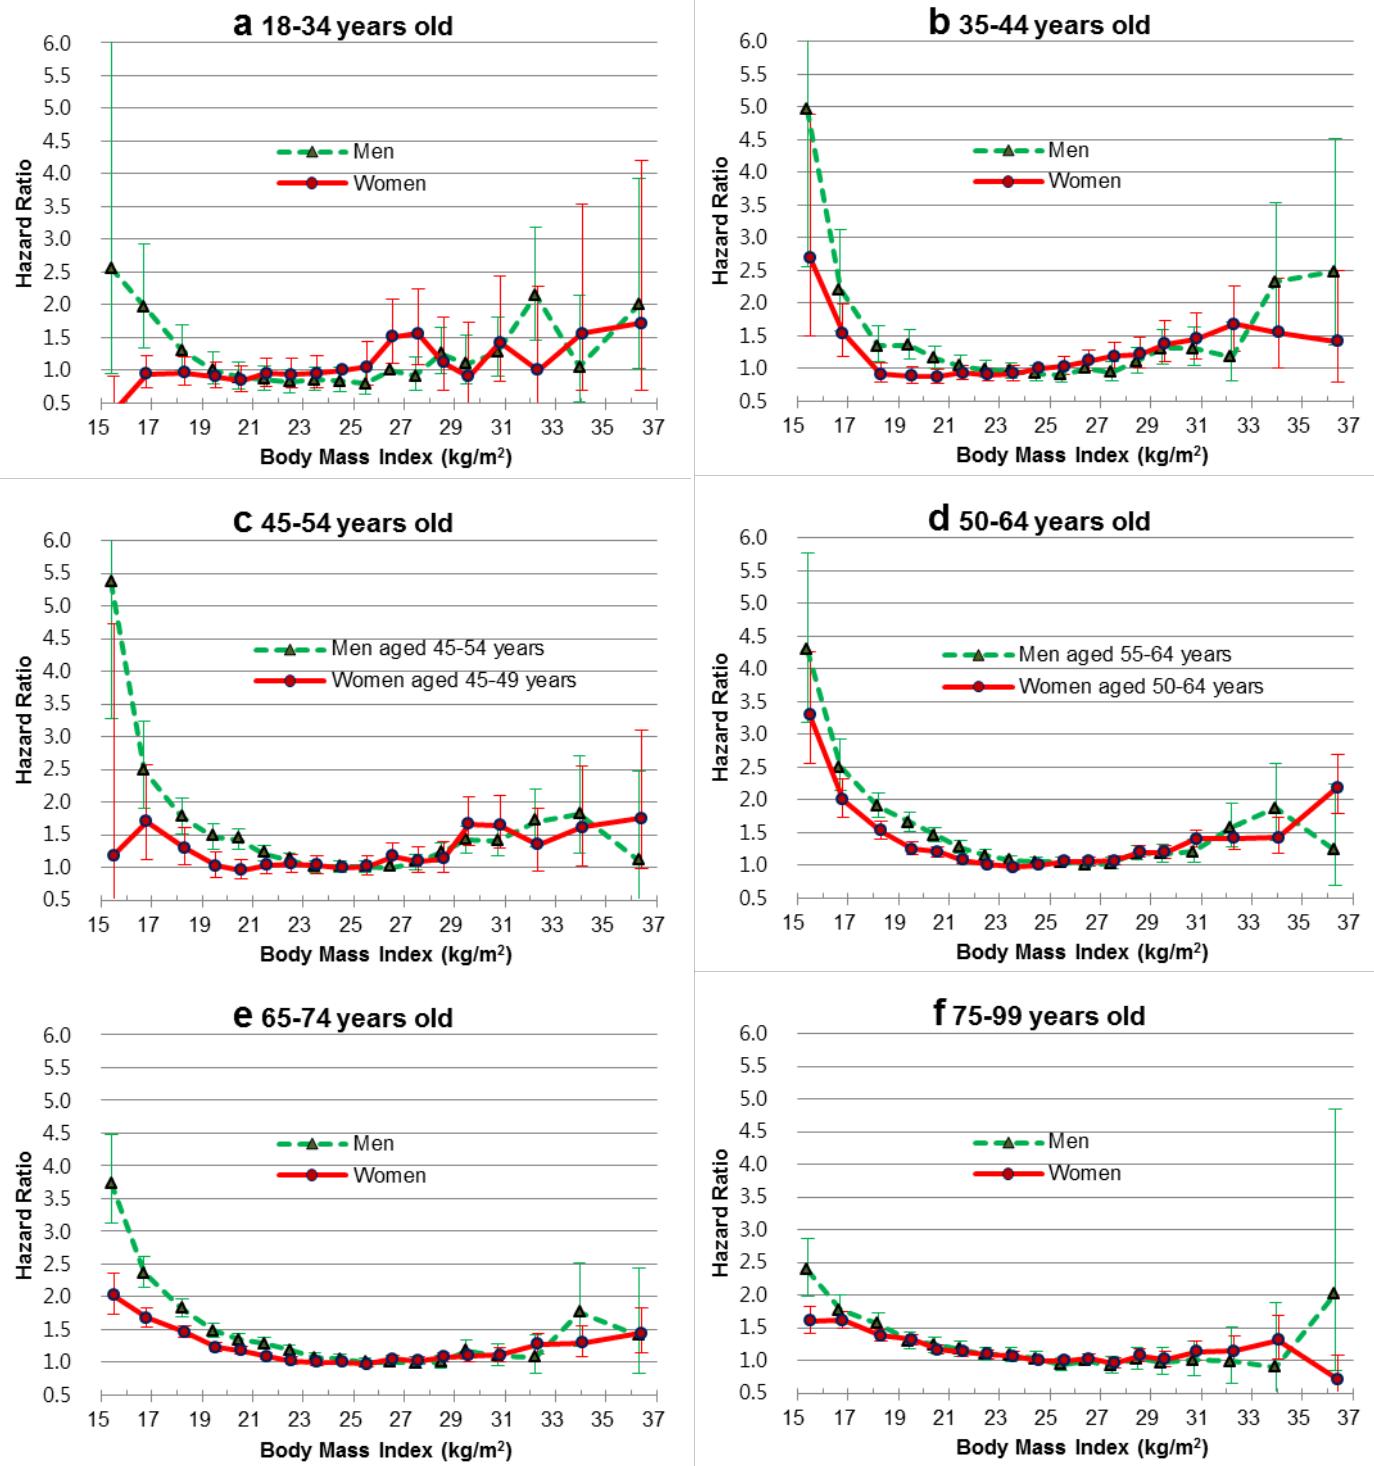

**Figure S5. Sex-age-specific hazard ratios of risk of death associated with body-mass index in never-smokers.**

Hazard ratios were calculated using Cox proportional hazard models. 18 categories of body-mass index (reference: 26.0-26.9 for men and 24.0-24.9 for women) were used. The midpoint was used as a representative value of each body-mass index category, except for both ends (15.5 and 36.4), for which the median of all participants was used. The analyses were adjusted for age and known pre-existing illness.

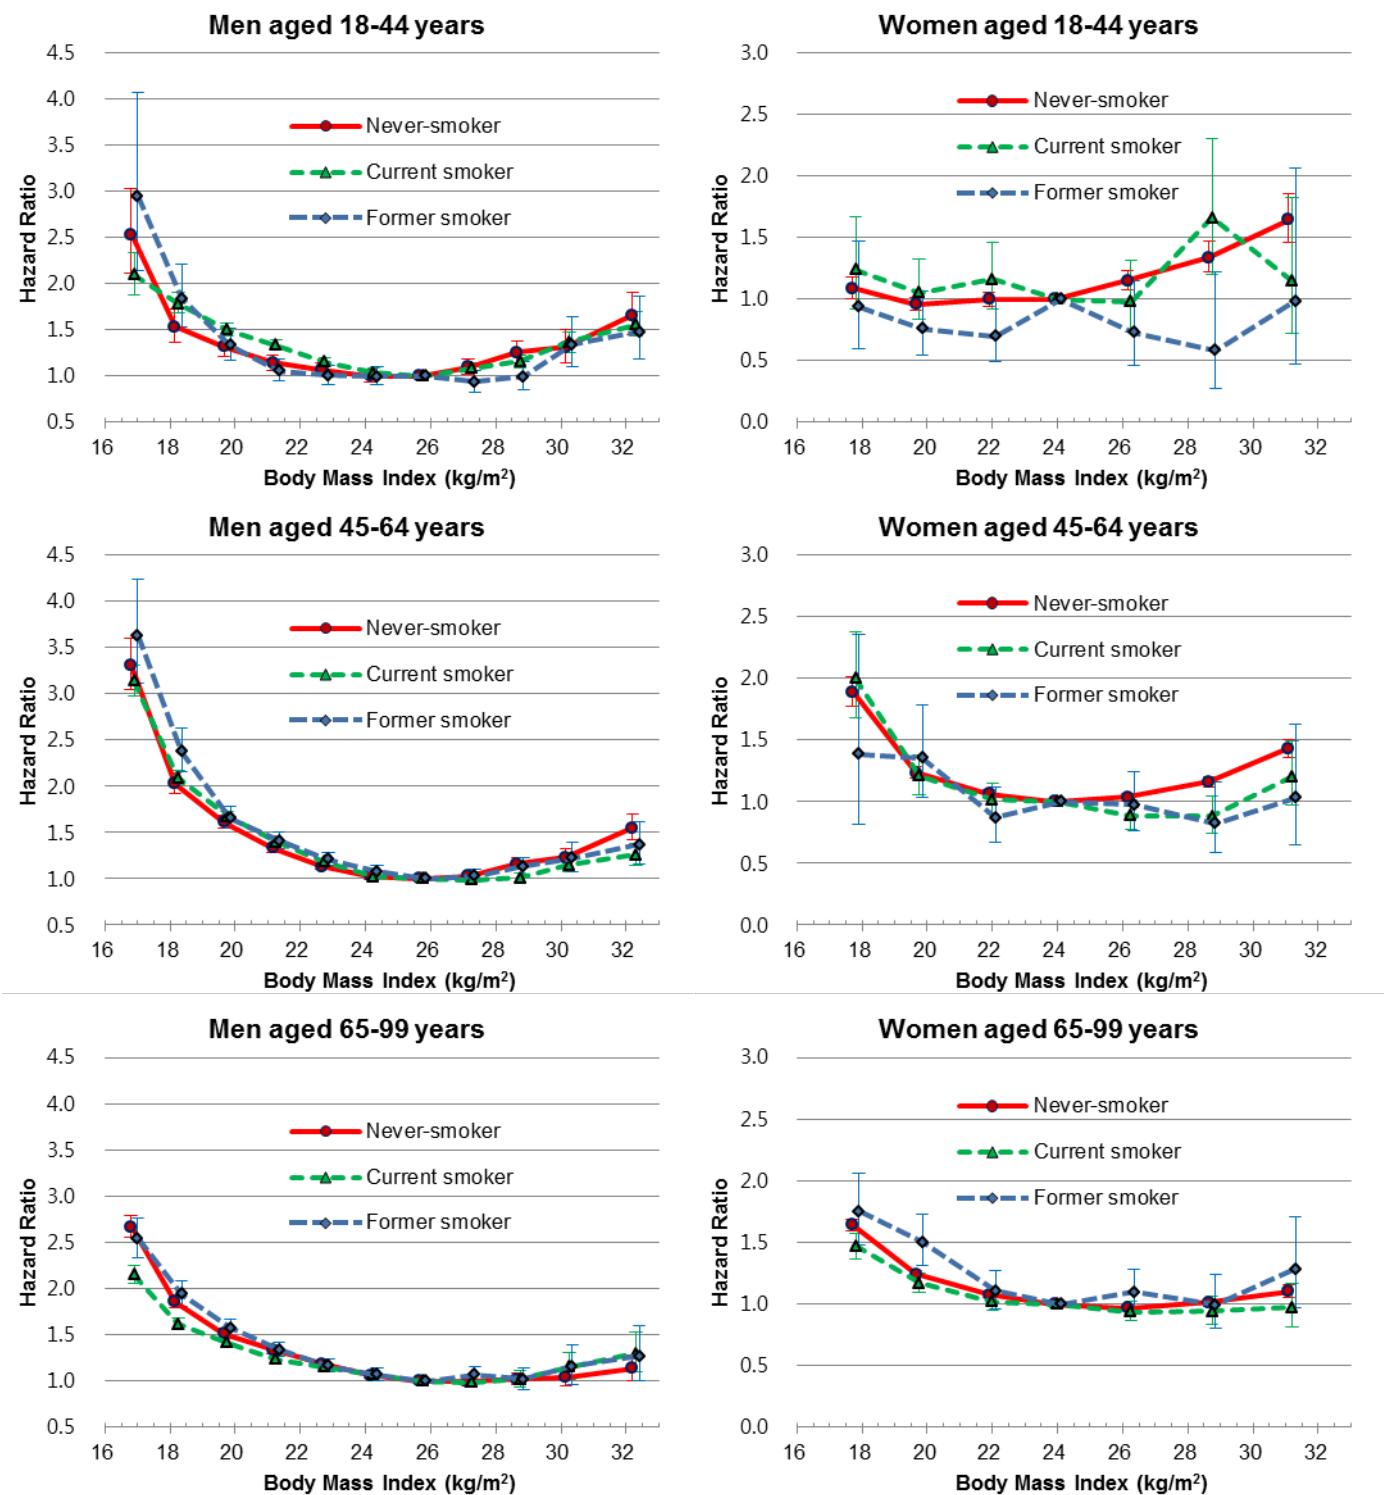

**Figure S6. Sex-age-specific hazard ratios of risk of death associated with body-mass index in never-smokers with no known illness.**

Hazard ratios were calculated using Cox proportional hazard models. 18 categories of body-mass index (reference: 26.0-26.9 for men and 24.0-24.9 for women) were used. The midpoint was used as a representative value of each body-mass index category, except for both ends (15.5 and 36.4), for which the median of all participants was used. The analyses were adjusted for age.

**Figure S7. Sex-age-specific hazard ratios of risk of death associated with body-mass index in never-smokers with no known illness who survived 5 years after enrollment.**

Hazard ratios were calculated using Cox proportional hazard models. 18 categories of body-mass index (reference: 26.0-26.9 for men and 24.0-24.9 for women) were used. The midpoint was used as a representative value of each body-mass index category, except for both ends (15.5 and 36.4), for which the median of all participants was used. The analyses were adjusted for age.

**Figure S8. Age-specific hazard ratios of risk of death associated with body-mass index in participants with no known illness according to sex and smoking status.**

Hazard ratios were calculated using Cox proportional hazard models. 11 categories of body-mass index for men (reference: 25.0-26.4) and 7 categories for women (reference: 23.0-24.9) were used. The midpoint was used as a representative value of each body-mass index category, except for both ends (16.9 and 32.3 for men [due to 11 groups]; 17.8 and 31.2 for women [7 groups]), for which the median of all participants was used. The analyses were adjusted for age.
