Supplemental Figures: 3 (Supplementary Figure 1-3)

Supplemental Tables: 5 (Supplementary Tables 1-5)

Supplementary Figure 1. Permutation analysis to determine optimal random sampling size. Histograms depict the frequency of estimations for mean Tau CI/mm² (PiD) and TDP %AO (FTLD-TDPC) obtained from 10,000 permutations for either 8 random tiles per cortical layer (24 total tiles) or 24 random tiles sampled independent of cortical layer in a case with mild, moderate and severe burden of pathology. Red dashed line represents the “true” mean value obtained from the full ROI and pink dashed lines represent the limits of 99% CI. Percentages represent the percentage of

permutation estimations falling outside of the 99% CI. We defined an optimum number of random tiles for sampling is defined as $\leq 10\%$ of permutation estimates outside of the 99% CI of the true signal; Thus, 24 tiles/image sampling scheme was chosen for analyses.

Supplementary Figure 2. Inclusion/area and %Area occupied digital image analysis for PiD and FTLD-TDPC. Photomicrographs depict representative images from STG (a-c, g-i) and MFG (d-f, j-l) from PiD (a-f) and FTLD-TDPC (g-l) cases using automated digital image analysis algorithms to detect (red-overlay) tau-positive PBs (b,e) and TDP-43 DNs (h,k) and total %AO with positive reactivity (red, orange, yellow) for tau (c,f) and TDP-43 (i,l). PiD had a lower burden of pathology in STG compared with MFG and conversely, FTLD-TDPC had a lower inclusion burden in MFG compared with STG. PiD had a large number of additional small dystrophic neurites included in %AO (c,f) not quantified with PB detection algorithms (b,e) while FTLD-TDPC had minimal additional small DNs in %AO not quantified in inclusion detection algorithms (h, k; asterisks). Scale bar= 100 μ m.

NC= negative control (IHC stain in absence of primary antibody).

Supplementary Figure 3. Comparison of HALO and IMAGEJ digital image analysis platforms. Photomicrographs depict representative images from digital image analysis comparison between HALO (rows A, C) and IMAGEJ (rows C,D) for Tau CI object detection (rows A, B) and TDP %AO (rows C,D). Conversion of optimal algorithms into equivalent IMAGEJ input parameters results in a similar color deconvolution between platforms (column 2) and Tau CI detection (black and white outlines in row B column 3) and TDP %AO (red overlay in row D column 3) to HALO

(red overlay in row A column 3 and yellow/orange/red overlay in row C column 3).
