

Supplemental Figure 1: Development related phenotypes of Scarlett/S42-IL107, Bowman/BW281 and Triumph/Triumph-IL

(A) Number of leaves emerged from the main shoot under long days (LDs) at the time of heading. (B) Phenotypes of the main shoot spike recorded at stamen primordium stage (W3.5, floret primordia per inflorescence) or at plant maturity (florets per spike, seeds per spike). Bars represent means \pm standard deviation over 5-15 plants. Significant differences ($p < 0.05$) between spring barleys and derived *Ppd-H1* introgression lines and between spike related phenotypes are indicated as asterisks and small letters on top of the charts, respectively.

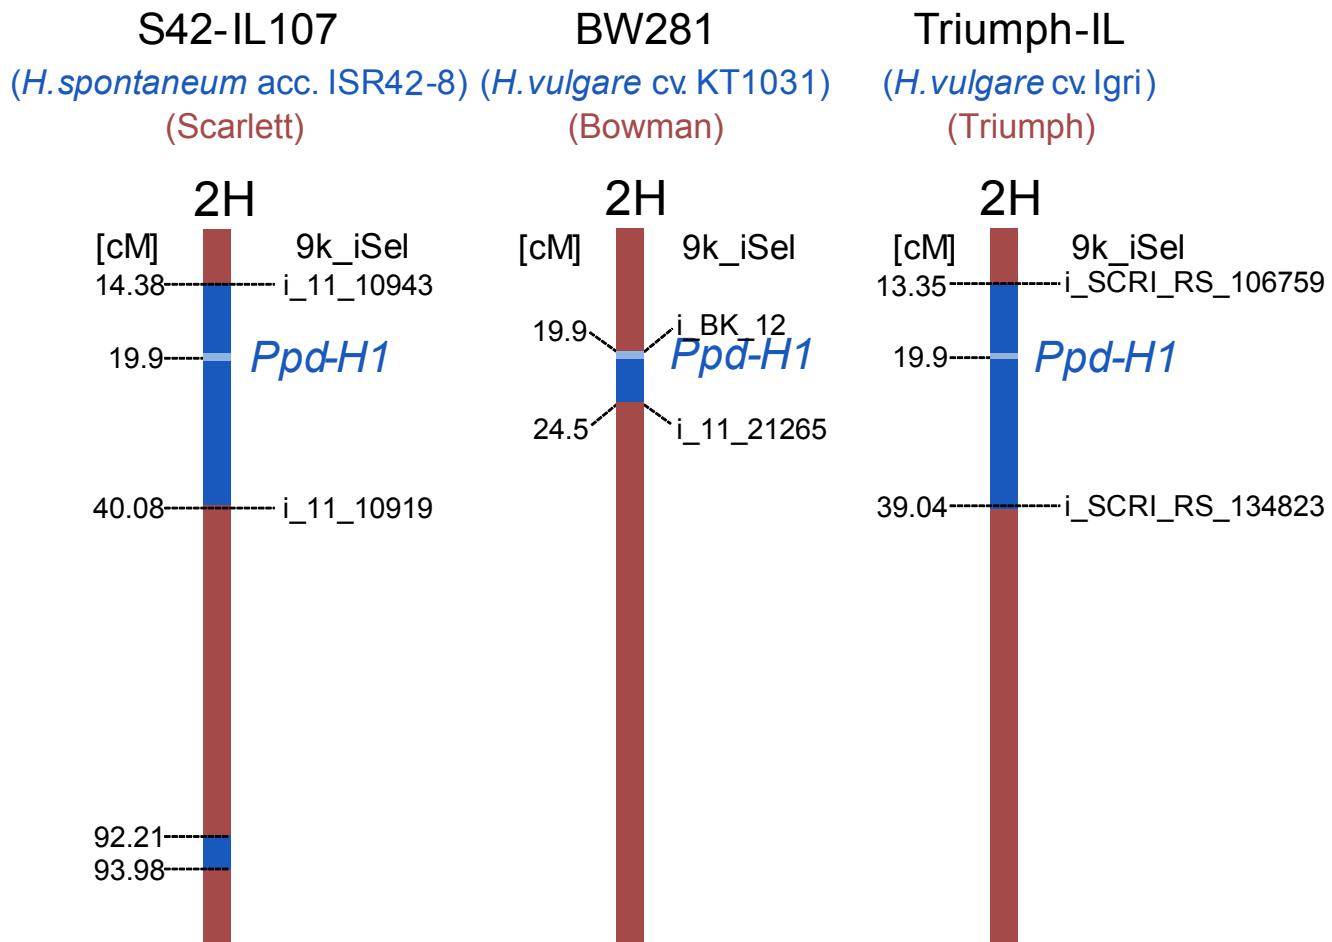

Supplemental Figure 2: Effects of the photoperiod during plant development on leaf emergence, stem elongation and spike traits of Scarlett and S42-IL107

Plants of Scarlett (black) and S42-IL107 (white) were grown under short-day (SD) or long-day (LD) conditions. At different stages of MSA development (W0.5 – W10), plants were transferred from (**left column**) LDs to SDs or from (**right column**) SDs to LDs and remained in the respective photoperiod until plant senescence. The following phenotypes of the main shoot were recorded for plants: **(A, B)** number of emerged leaves at heading or at main shoot senescence; **(C, D)** height; **(E, F)** spike length; **(G, H)** floret number per spike. Bars represent means \pm standard deviation over 3 plants. Significant differences ($p < 0.05$) between genotypes transferred from SDs to LDs and vice versa at the same developmental stage are indicated by asterisks above bar graphs.

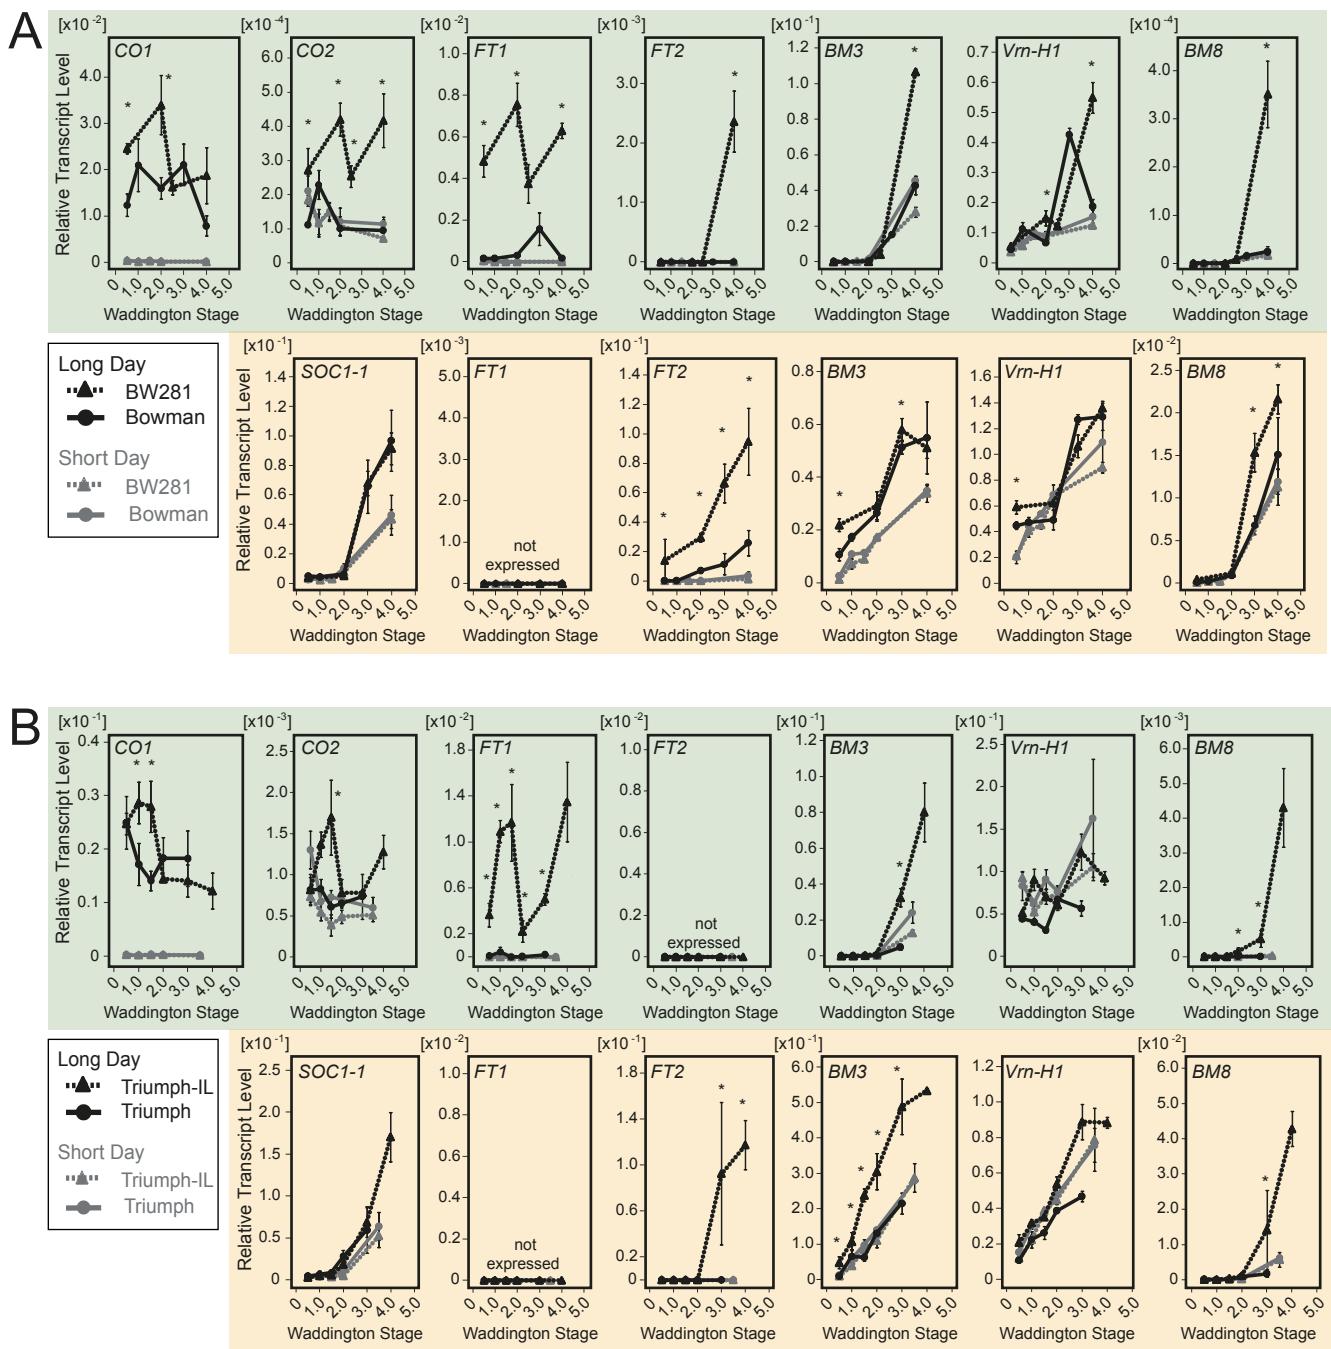

Supplemental Figure 3: Development of the main shoot apex of Scarlett and S42-IL107

Developmental stage of the apex (W: Waddington stage) and number of leaves emerged from the main shoot are reported. Plants were grown under short-day conditions (SD) or transferred to long days (LDs) seven days after germination (Day 0). Blue labels indicate stages, at which leaf and apex samples were harvested for transcriptome profiling using RNA sequencing. White bars (500μm), blue bars (1mm).

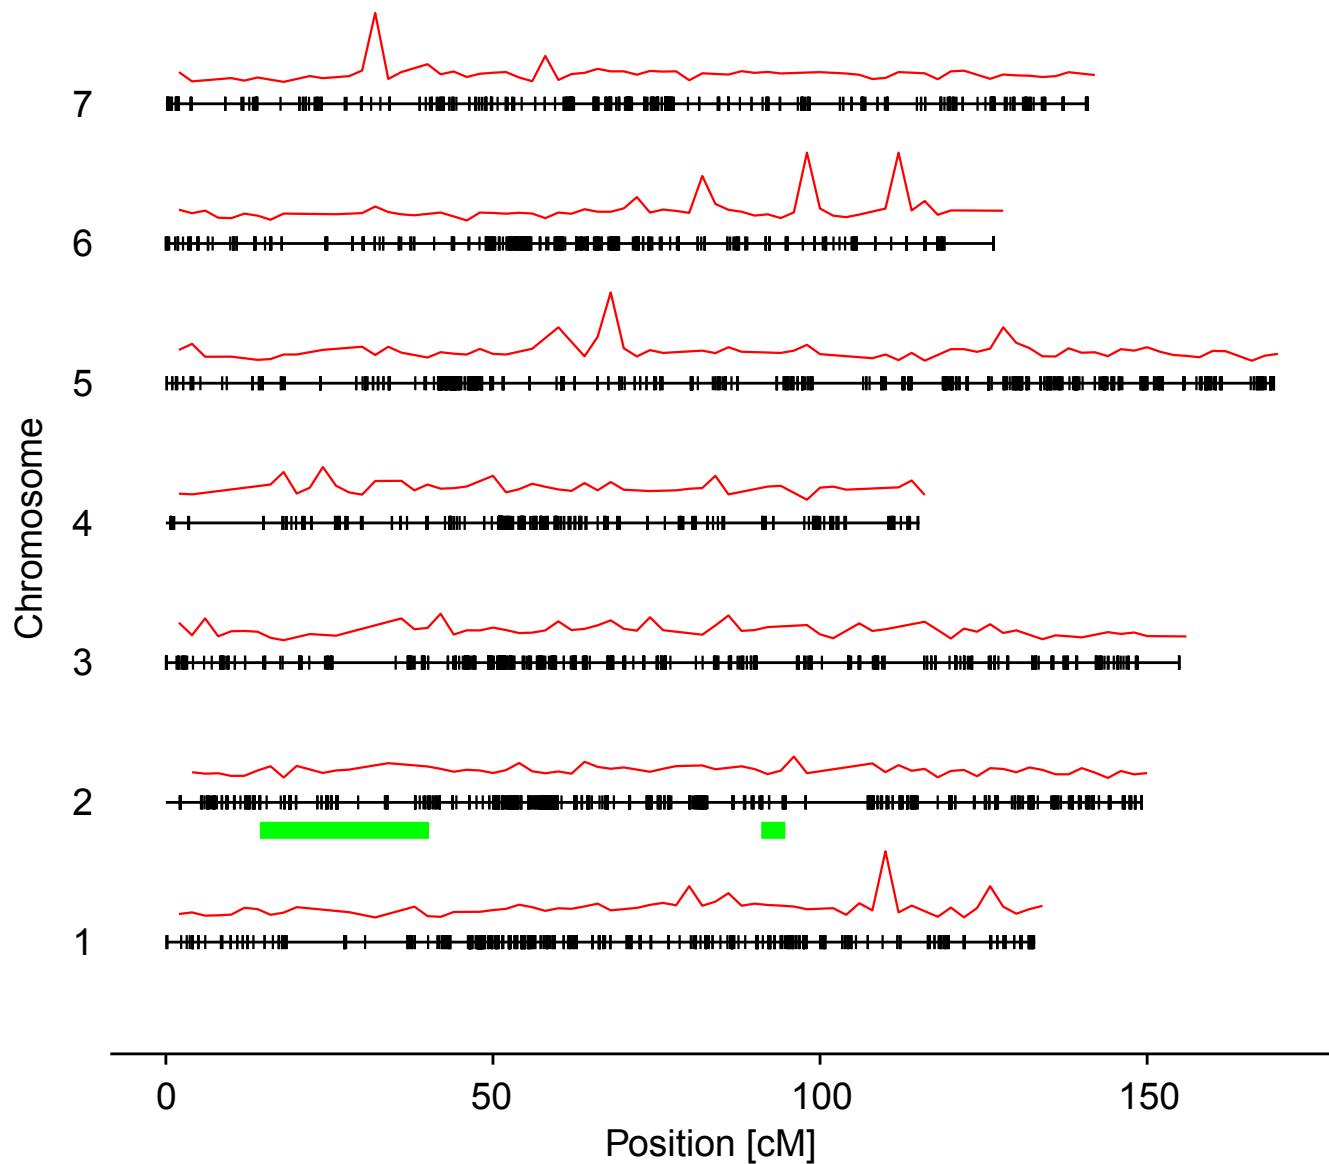

Supplemental Figure 4: Size and flanking markers of *Ppd-H1* introgressions on chromosome 2H.

Donor parents for the photoperiod-responsive *Ppd-H1* allele of the introgression lines and their respective spring barley background genotypes are indicated above each chart. Introgression lines were genotyped with the 9k-iSelect chip from Illumina. Flanking marker positions of the introgressions are given relative to the POPSEQ map (Marscher et al., 2013).

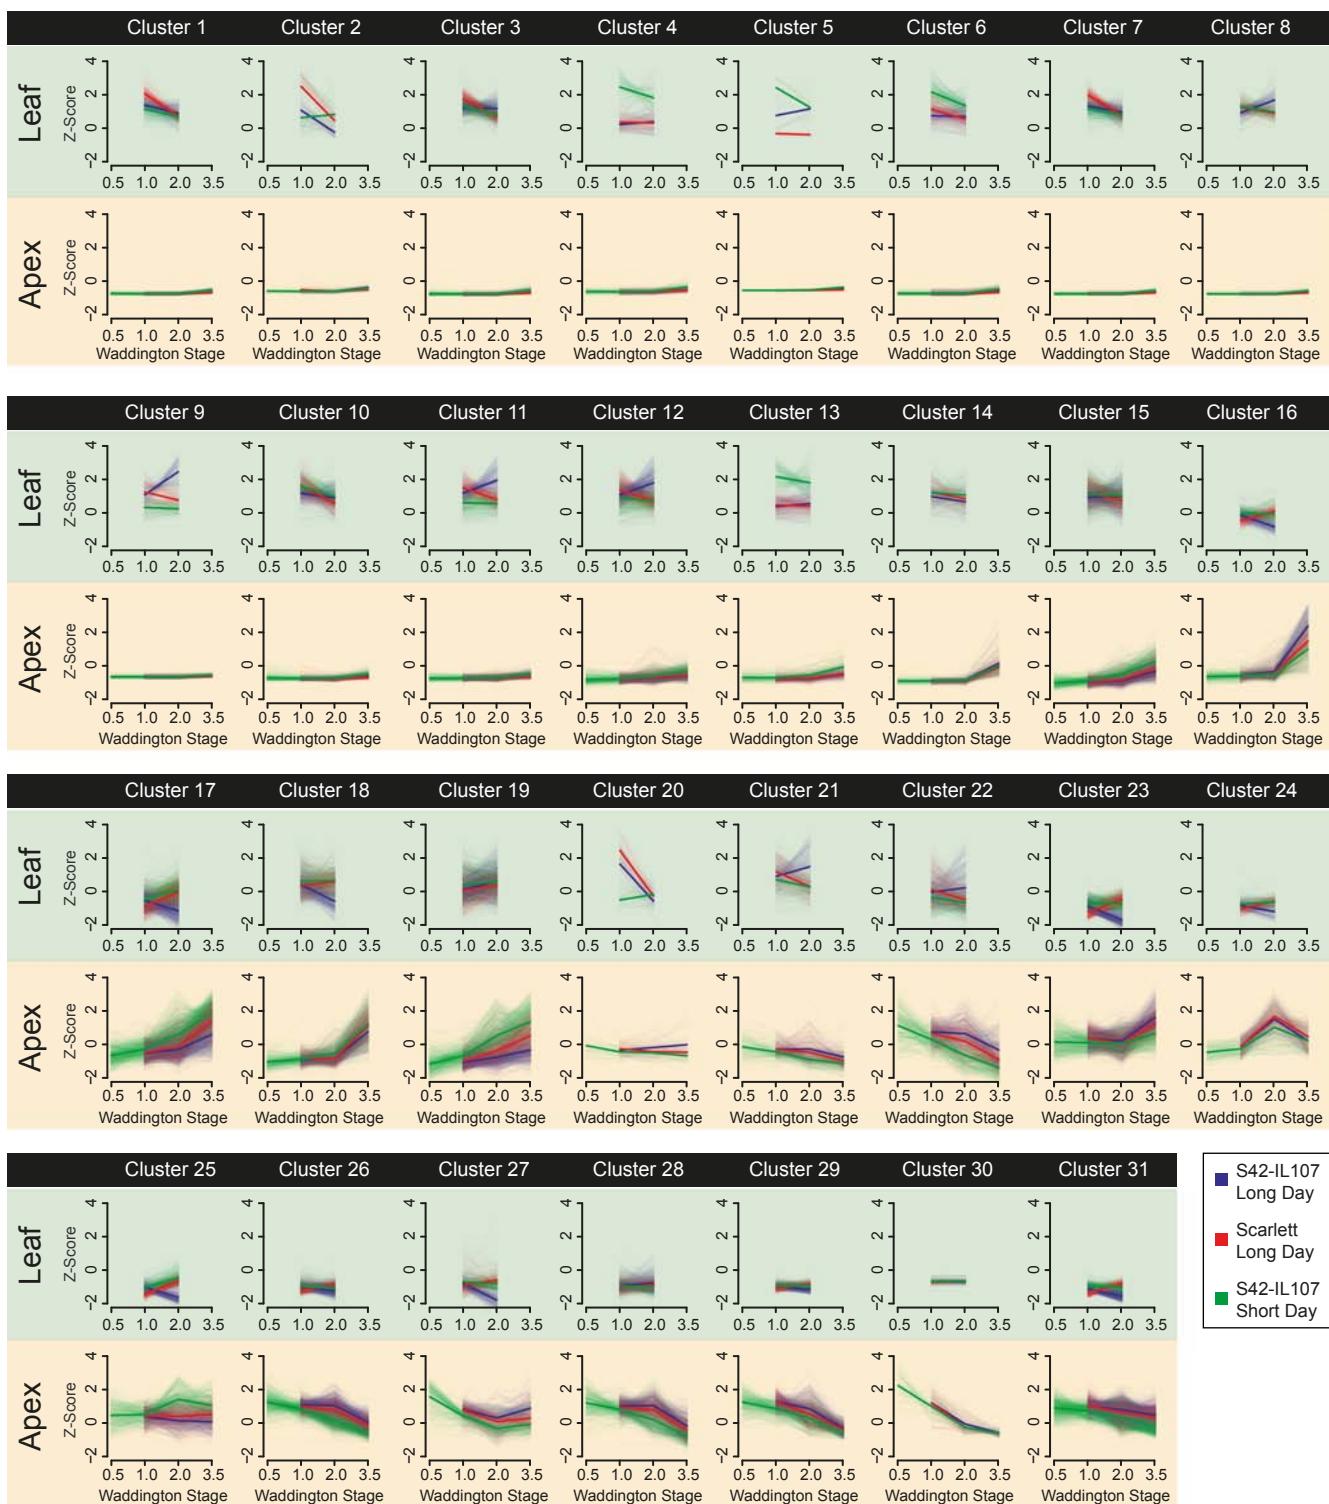

Supplemental Figure 5: Validation of transcript levels in leaves and shoot apices of Bowman/ BW281, Triumph/Triumph-IL

Quantification of transcript levels by quantitative real time PCR (RT-qPCR) in leaf samples (green) and samples enriched for apex tissue (orange) at different stages of plant development. Samples were harvested from the barley genotypes (**A**) Bowman and BW281 and (**B**) Triumph and Triumph-IL. Transcript levels are demonstrated relative to the transcript abundance of *Actin*. Error bars indicate the standard deviation over three biological and two technical replicates. Asterisks highlight significant differences ($p < 0.05$) between transcript levels of BW281 and Bowman or Triumph-IL and Triumph, respectively, when plants were at the same developmental stage and grown under long-day conditions.

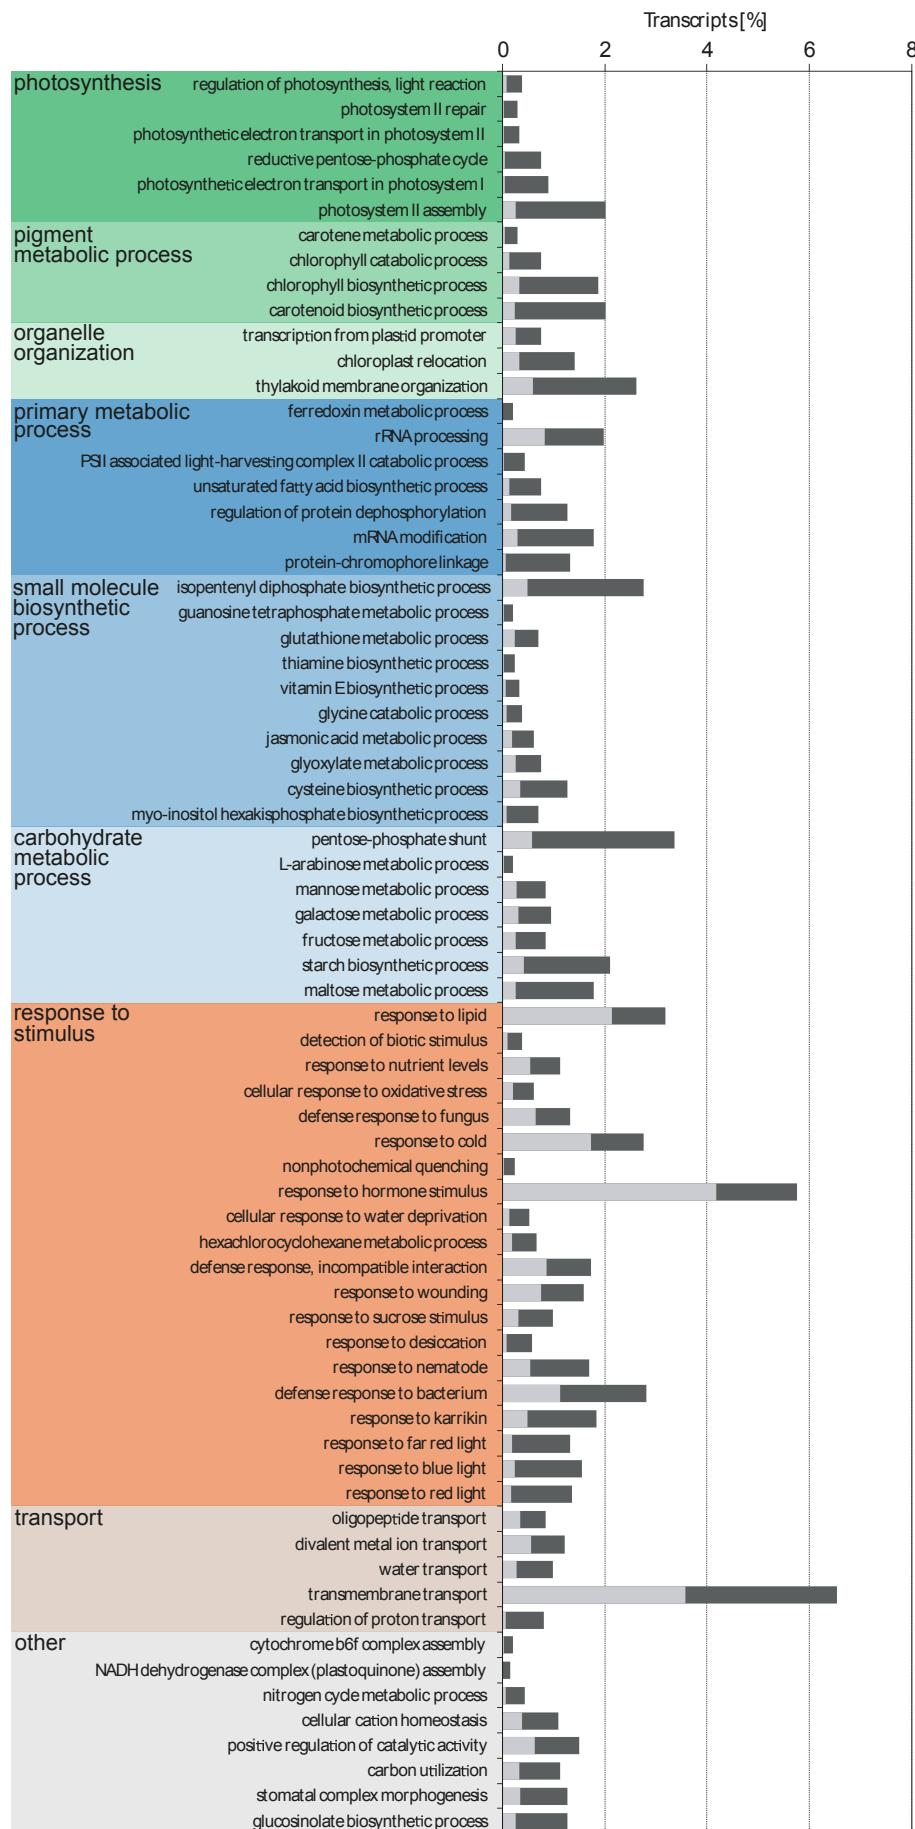

Supplemental Figure 6: Distribution and density of differentially expressed transcripts (DETs) along the barley chromosomes.

Seven barley chromosomes are depicted as horizontal black lines. The DETs are shown as vertical black lines plotted on the chromosomes. Location of the S42-IL107 introgression region is shown as green rectangles below the chromosome 2H. The density of the DETs is plotted as red lines above the chromosomes. Positions are given in centimorgans (cM) according to the PopSeq map (Mascher et al., 2013).

**Supplemental Figure 7: Expression profiles of 7604 DETs in 31 coexpression clusters**

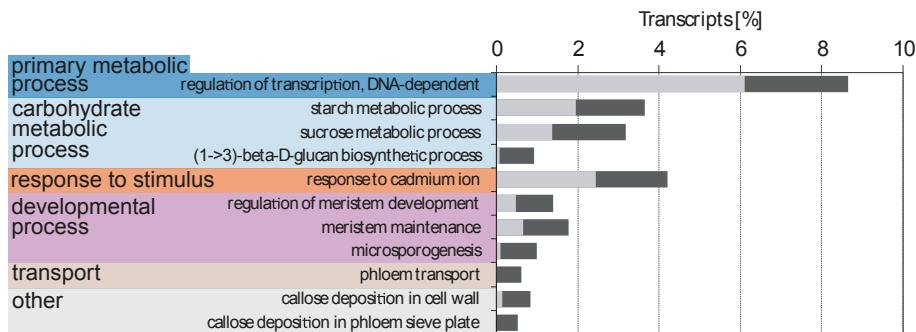

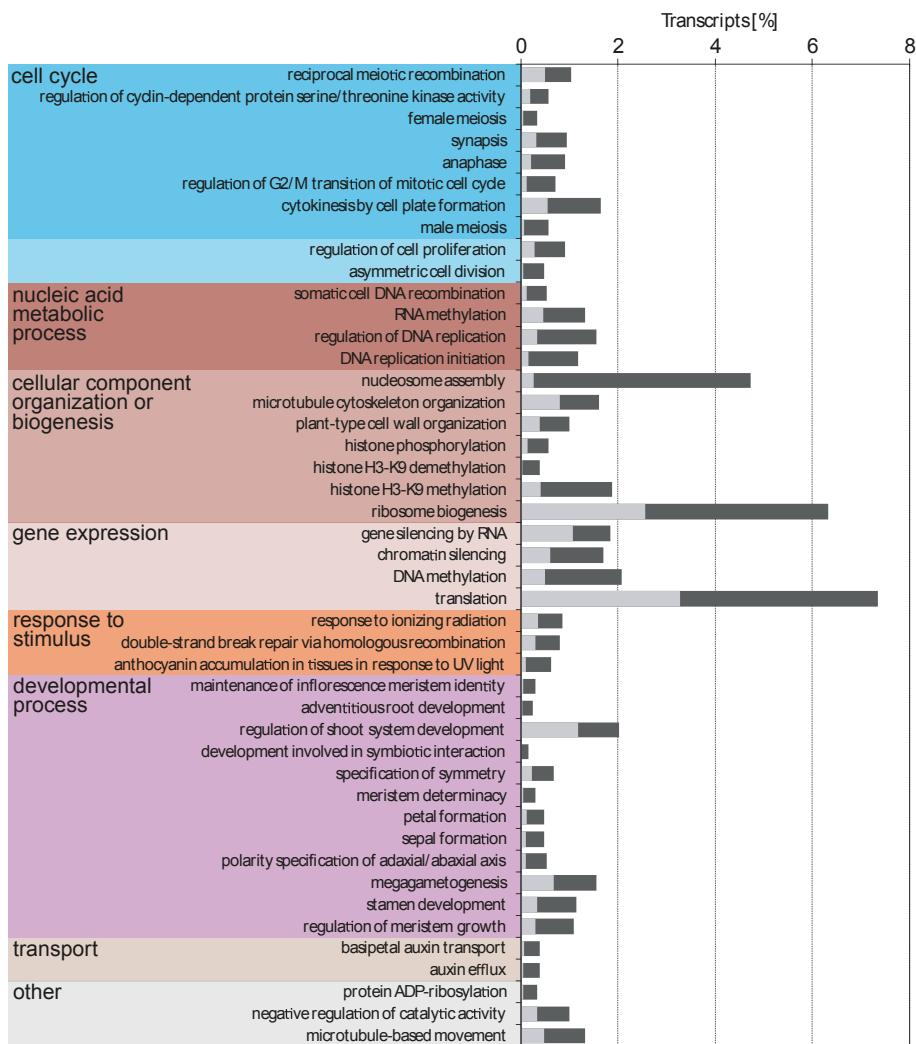

Coexpression clusters of 7604 differentially expressed transcripts (DET). Expression levels for individual transcripts (light colors) and mean expression level across all transcripts within each cluster (bright color) were plotted. Coexpression plots depict transcript expression patterns in leaves (green) and apices (orange) as mean centered and scaled transcript levels (Z-Score). Detailed statistics for each cluster are presented in Supplemental Table 20.

A

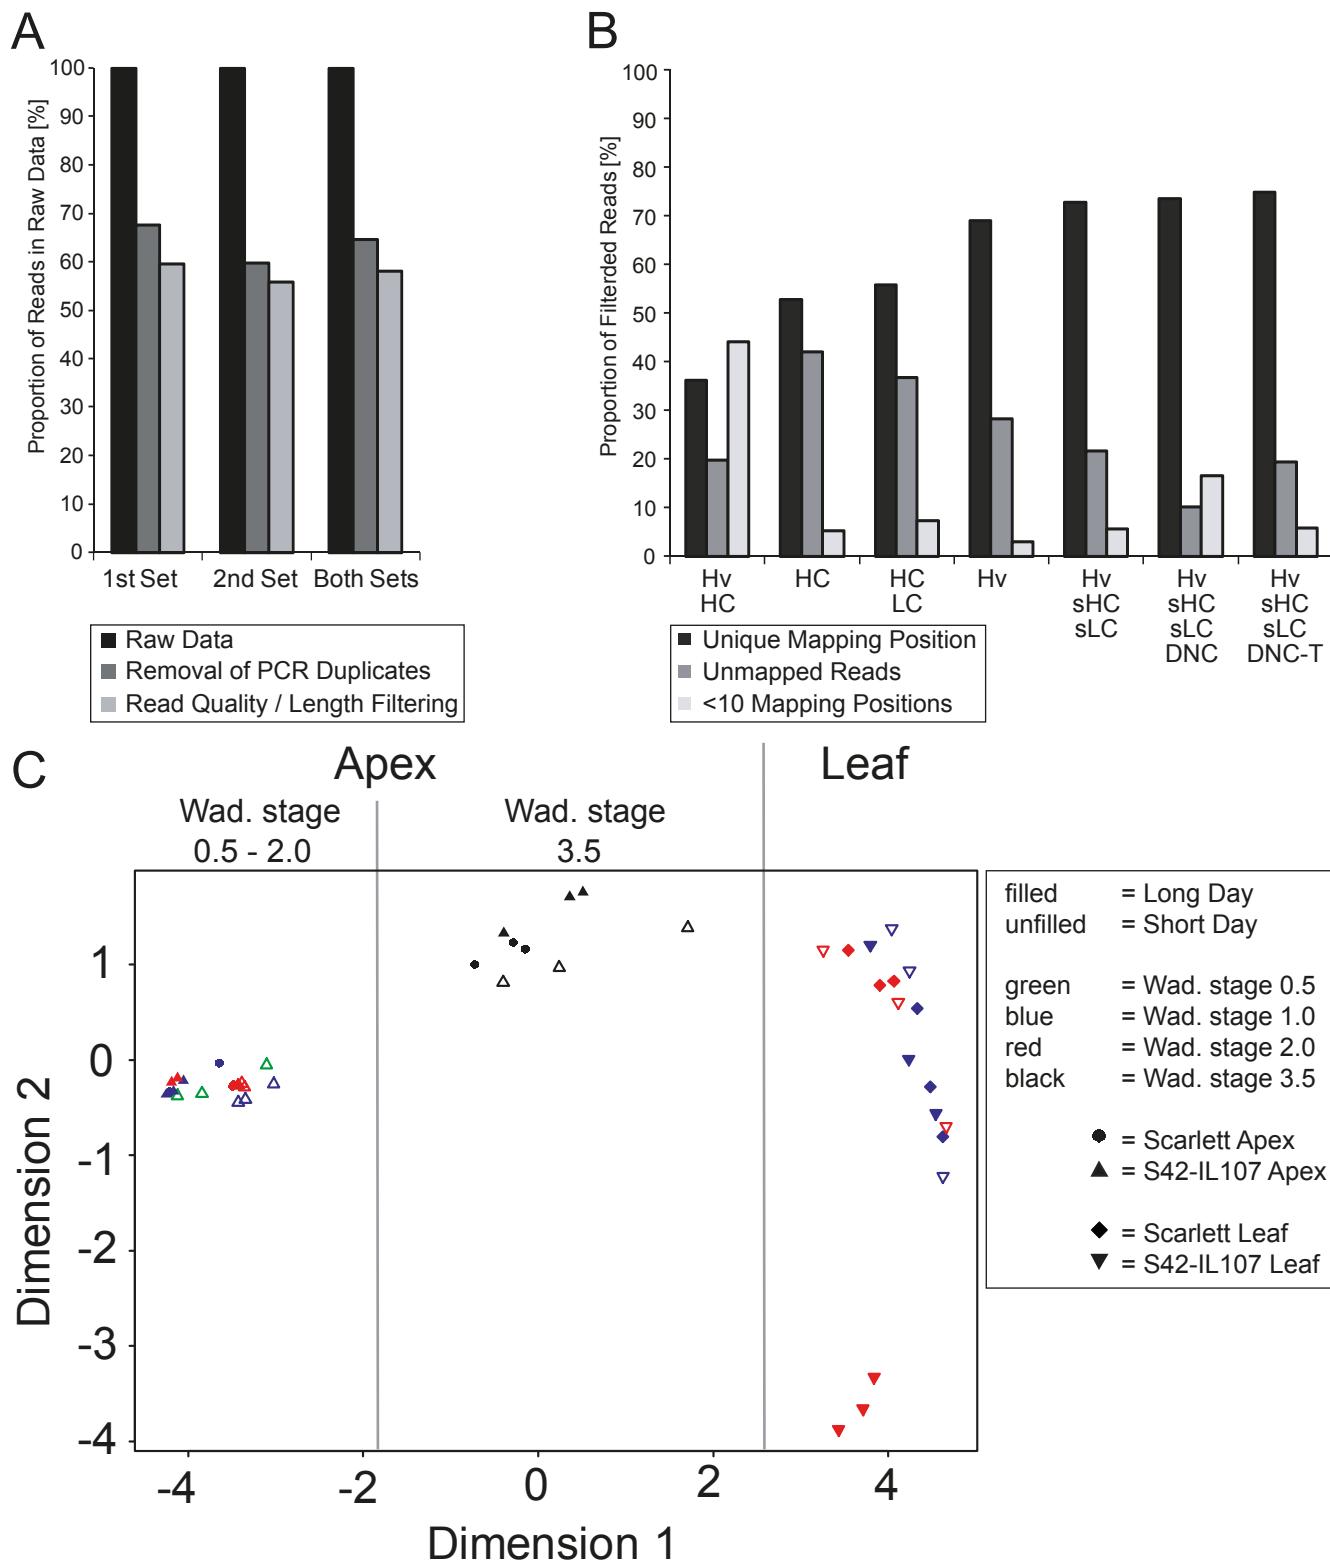

Supplemental Figure 8 (part 1): Overrepresentation of Gene Ontology (GO) terms among transcripts in coexpression clusters I-III

Legend see next page

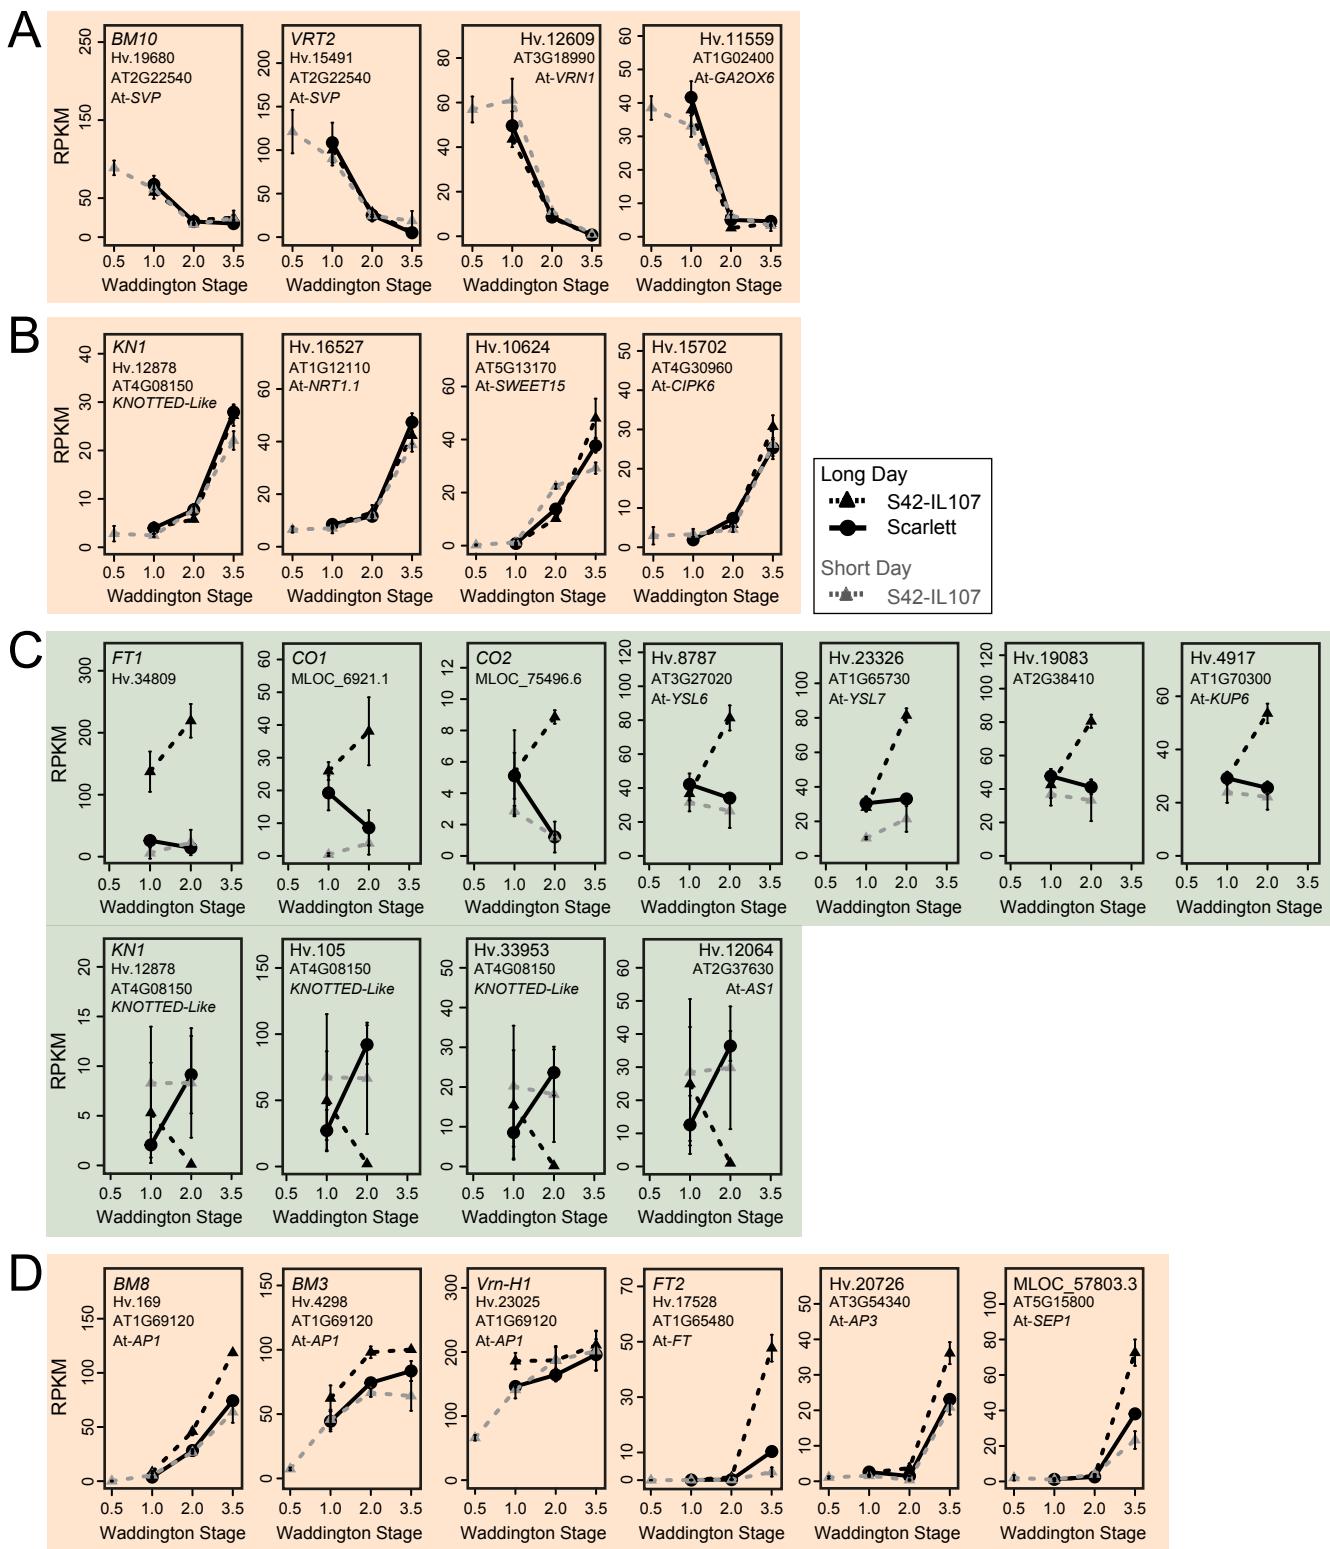

B**C**

Supplemental Figure 8 (part 2): Overrepresentation of Gene Ontology (GO) terms among transcripts in coexpression clusters I-III

Overrepresented GO terms assigned to biological processes for transcripts coexpressed within (**A**) cluster I, (**B**) cluster II and (**C**) cluster III, respectively. Clusters represent transcripts predominantly expressed in leaves (cluster I), shoot apices (cluster III) or equally expressed in both tissues (cluster II). Significant (FDR<0.05) leaf nodes of the GO-tree were summarized to common parental GO-terms (colored). Bars indicate the relative abundance of transcripts assigned to the GO-terms in the test set (dark grey) and the reference set (light grey), respectively.

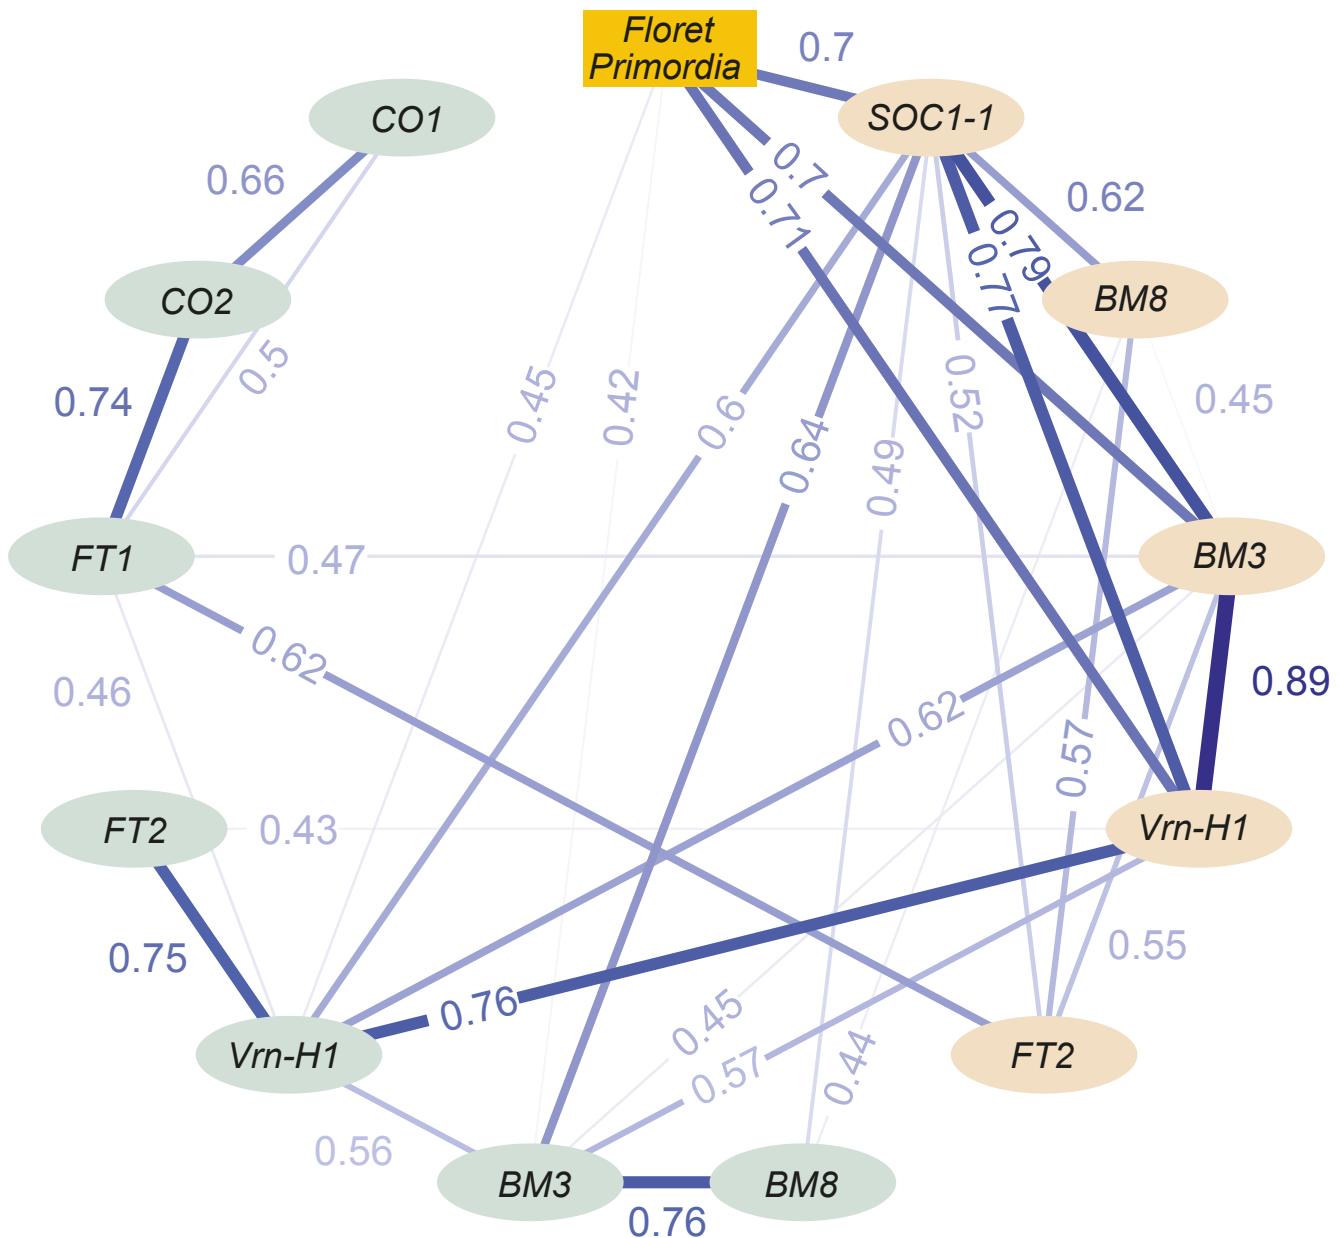

**Supplemental Figure 9: Overview of RNA sequencing statistics**

(A) Quality- and length-based filtering of raw sequencing reads (100bp, single-end, Illumina), derived from two independent sequencing runs. Reads of libraries A to X (1st set) and of libraries A1-AE1 (2nd set) retained after filtering. See Supplemental Table 18 for detailed information on the libraries. **(B)** Proportion of filtered reads mapping to the reference sets of different transcript combinations. Hv: barley NCBI UniGene set; HC: high confidence gene set; LC: low confidence gene set; sHC/sLC: selected subset of unique HC or LC; DNC, *de novo* contigs assembled from unmapped Illumina reads; DNC-T, selected *de novo* contigs with BLASTx hit in the Triticeae. **(C)** Unsupervised clustering of RNA samples in two dimensions by multidimensional scaling.

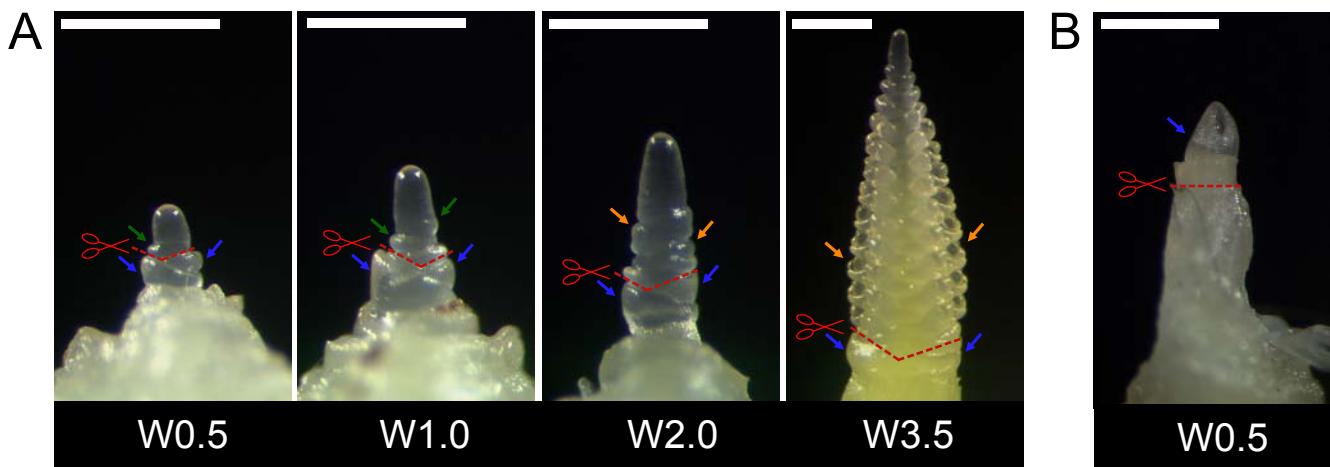

Supplemental Figure 10: Expression patterns of selected transcripts in leaves and shoot apices of Scarlett and S42-IL107 determined by RNA sequencing (RNA-seq)

RNA-seq derived expression data of transcripts (**A**) downregulated or (**B**) upregulated during MSA development independent of the genotype and photoperiod or differentially regulated between photoperiods and between genotypes in (**C**) leaves or (**D**) shoot apices. Normalized expression values are reported in reads per kilo base per million (RPKM). Error bars indicate standard deviation across two to three independent RNA samples.

**Supplemental Figure 11: Correlation network for gene expression data in leaves and shoot apices**

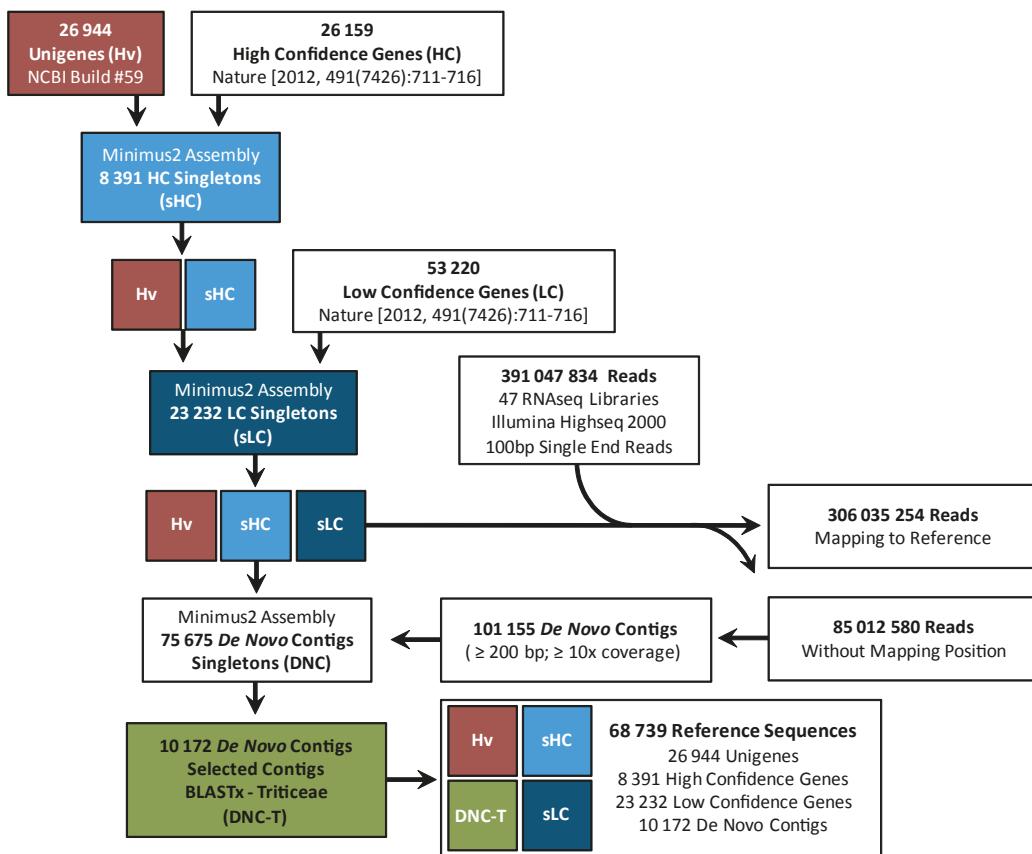

Correlation network between transcript levels of flowering time genes in leaf and shoot apex samples and number of floret primordia emerged at the shoot apex during early stages of shoot apex development. Transcript abundance was determined by RT-qPCR in leaves (green ellipses) and shoot apex enriched tissue (orange ellipses) of Scarlett, Bowman, Triumph and their derived *Ppd-H1* introgression lines (see also Figure 3D+E and Supplemental Figure 5). Pearson correlation coefficients of $r > |0.4|$ and $FDR < 0.05$ are indicated as blue lines connecting the individual transcripts.

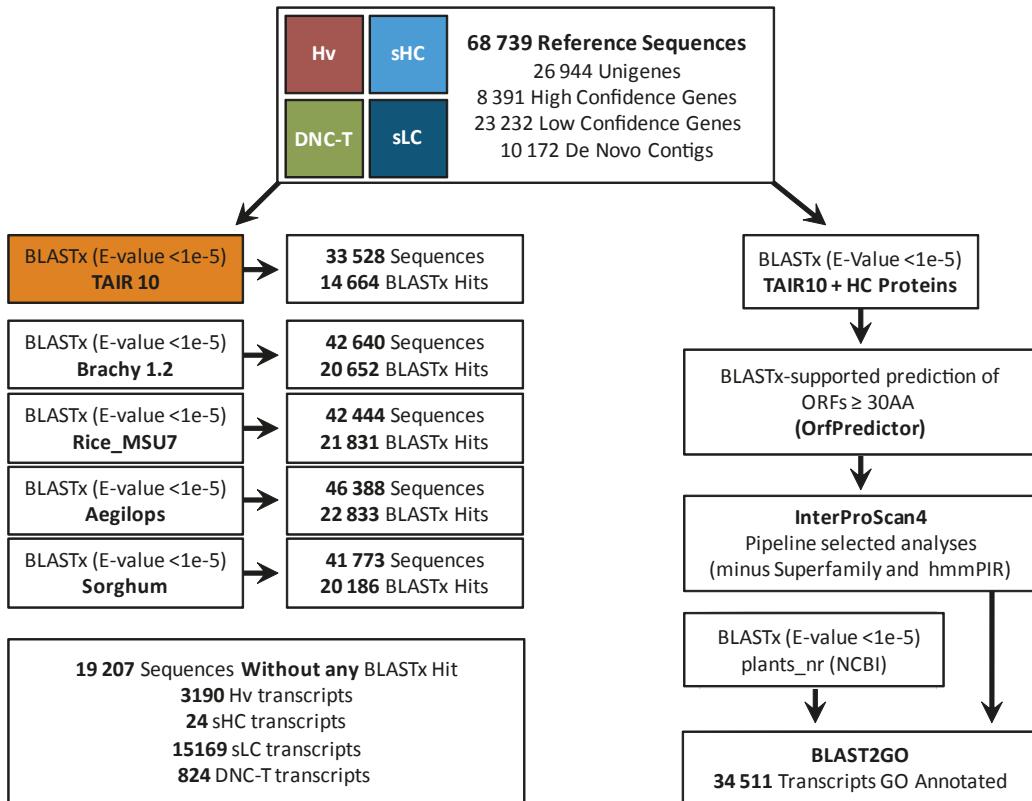

Supplemental Figure 12: Representative main shoot apices dissected for RNA extraction

Total RNA was extracted from pools of isolated shoot apices including the tissue above the red dashed lines. Waddington stages (W) of harvested shoot apices are indicated below the pictures. White bars represent 500 μ m. **(A)** Shoot apex samples harvested for RNA sequencing comprised dissected tissues of the apical dome, young leaf primordia (green arrows) and floret primordia (orange arrows). Older leaf primordia (blue arrows) and basal parts of the shoot apex were excluded. **(B)** Apex enriched tissue harvested for RT-qPCR analysis at different stages of development also included older leaf primordia and basal parts of the shoot apex as indicated for a vegetative shoot apex at W0.5.

B

Supplemental Figure 13 (part 1): Schematic representation of the RNA sequencing pipeline
Legend see next page

**Supplemental Figure 13 (part 2): Schematic representation of the RNA sequencing pipeline**

(A) Selection of transcripts used as reference sequences in the read mapping step prior to differential gene expression analysis. **(B)** Annotation of transcripts in the reference set is based on BLASTx results against different plant protein databases (left panel) and retrieval of Gene Ontology terms with Blast2GO software (right panel). **(C)** Summary of the differential gene expression and coexpression analysis using the edgeR- and MBCluster.Seq-packages of the R statistical software, respectively. DET: Differentially expressed transcripts; Hv, Unigenes: Barley NCBI UniGene set; HC: High confidence gene set; LC: Low confidence gene set; sHC/sLC: selected subset of unique HC or LC.

Supplemental Table 1: Slopes of broken-line regressions performed on MSA development and floret primordia induction in Scarlett and S42-IL107 under SD and LD

Phenotype	Photoperiod	Genotype	Segment of Regression Line	Slope	St.Err.	Upper 95%-CI ¹	Lower 95%-CI ¹

¹ Transcript Sequences available at the National Center for Biotechnology Information (NCBI: <http://www.ncbi.nlm.nih.gov>) and at the PGSB barley genome database (<http://pgsb.helmholtz-muenchen.de/plant/barley>), respectively.

Supplemental methods

Design of the reference sequence

To obtain a comprehensive reference sequence, we compared the mapping efficiency of the filtered reads against two sets of transcript clusters available for barley.

Recently, the International Barley Genome Sequencing Consortium (IBGSC) published the draft genome sequence of barley including the transcribed gene space assigned to a set of 26,159 annotated high-confidence genes (HC) and a set of 53,220 low-confidence genes (LC) (IBGSC, *Nature* 2012). Sequences of the HC and LC were downloaded from the Barley project webpage (ftp://ftpmips.helmholtz-muenchen.de/plants/barley/public_data/genes/, sequence version of March 23rd, 2012). Secondly, a cluster of 26,944 barley UniGenes (UniGene build #59 at NCBI), henceforth referred to as unigenes, was downloaded from NCBI (ftp://ftp.ncbi.nih.gov/repository/UniGene/Hordeum_vulgare/) and used for comparison.

Filtered reads of all libraries were combined and mapped against the respective reference sequences using the RNA-Seq Analysis function of CLC with default parameters. Test mappings were performed on the unigenes, HC and LC sets alone and on various combinations of those. In addition, we assembled *de novo* contigs using CLC *de novo* assemble tool.

To determine the appropriate core reference set for our study, we estimated the extent of sequence redundancy within the different reference sets using BLASTn. Redundancy was defined as a proportion of blast hits longer than 100bp with 97% identity. Furthermore, as an estimate for sequence redundancy, we extracted the proportion of reads with multiple mapping positions (≤ 10 positions) within a respective reference set. In addition to low sequence redundancy, we expected a comprehensive set of reference sequences to yield a high proportion of reads with unique mapping positions and a low percentage of reads assigned as unmapped, i.e. reads without mapping position or mapped to more than ten locations.

The unigenes were selected as a core set due to its lowest sequence redundancy and highest proportion of uniquely mapping reads as compared to the HC and LC datasets (Supplemental Fig. 9B), e.g. in total we mapped 280,871,398 reads against the unigene set, of which 269,468,960 reads had unique and 11,402,438 reads had multiple mapping positions. Against transcripts of the HC dataset, we mapped 226,964,864 reads in total with unique and multiple mapping positions for 206,228,484 reads and 20,736,380 reads, respectively. Thus, other datasets were added to transcripts of the unigene set in the following order of priority: HC, LC, *de novo* contigs.

Redundancy in the combined datasets was eliminated using Minimus2 software with parameters set to 130bp overlap and 97% minimum identity. Filtering transcripts appropriately yielded 8,391 HC (sHC) and 23,232 LC (sLC) progressively added to the unigenes.

To allow the identification of new transcripts specific for shoot apex tissue used in our study, we used CLC *de novo* assembly tool with default parameters to construct a set of 473,651 *de novo* contigs (DNC) from 85,0125,80 reads, which did not map to a reference sequence constructed from unigenes, sHC and sLC. Contigs were filtered for a minimum length of 200bp and a 10X average coverage. A set of 10,172 DNC with BLASTx hits in the *Triticeae* family (E-value $\leq 10^{-5}$), henceforth DNC-T, was selected from the 75,675 DNC identified as Minimus2 singletons. A schematic representation of the pipeline used to construct the reference sequence is presented in Supplemental Fig. 13A.

In summary, a final set of 68,739 transcripts, consisting of 26,944 unigenes, 8,391 sHC, 23,232 sLC and 10,172 DNC-T, was used as a custom reference for the RNA-sequencing analysis. Using this as reference set, 80.6% (315,108,855 reads) of the quality filtered reads could be mapped in total with 74.9% (292,699,606 reads) having unique and 5.7% (22,409,249 reads) multiple mapping positions.

The reference set was annotated using BLASTx against protein databases of *Arabidopsis* (TAIR version 10), *Brachypodium* (*Brachypodium distachyon*, Project version 1.2), Rice (MSU Rice Genome Annotation Project release 7) and *Sorghum* (1.4, Paterson et al., 2009) with cut-off E-value 10^{-5} .

The open reading frames (ORF) of barley transcripts were predicted using the OrfPredictor software guided by the BLASTx results against TAIR (≥ 30 aa, Min et al., 2005). Conserved domain annotation of the translated ORFs was performed using InterProScan4 software (Hunter et al., 2011). These data together with the top 20 BLASTx hits against the *Viridiplantae* sub-set of NCBI ‘nr’ database were used to determine gene ontology (GO) terms for the reference barley transcripts using Blast2GO pipe 2.5.0 (Conesa et al., 2005). An overview the reference sequence annotation pipeline is depicted in Supplemental Fig. 13B.
