

age and mother's HIV-status. Children born to HIV-infected mothers had a higher prevalence of TST positivity in the 24-35 month age-category ($p=0.013$) and the 36-60 month age group ($p=0.001$) compared to the children born to HIV-uninfected mothers in the same age-group. A positive TST is defined as induration ≥ 10 mm.

Figure 2: Quantiferon Gold-In-Tube (QFT) and Tuberculin Skin (TST) positivity among children ≤ 60 months, using different definitions for TST cut offs for positivity.

*age-specific cut-off proposed by Chan et al.²⁸ (positive TST defined as ≥ 21 mm from 0-1 years, ≥ 18 mm from age 2-3 years, and ≥ 13 mm from 4-5 years).
