Supplemental Information

Rbfox proteins regulate microRNA biogenesis by sequence specific binding to their precursors and target downstream Dicer

Yu Chen, Lorena Zubovic, Fan Yang, Katherine Godin, Tom Pavelitz, Javier Castellanos, Paolo Macchi, Gabriele Varani

Paramagnetic spin-labeling of RNA and PRE data collection

A previously published protocol¹ was followed to attach the 3-(2-iodoacetamido)-proxyl spin label to a chemically synthesized 46 nucleotide pre-miR-20b containing a single 4thio Uracyl 43 base (purchased from Dharmacon). This RNA is shorter than the completepre-miR-20b but the lower part of the structure is too distant from the loop to be contacted by the protein. Complete coupling was achieved by overnight reaction at room temperature, as monitored by complete shift of the maximum in UV absorption to ~320 nm. The protein-RNA complex were prepared by adding pre-dyalized paramagnetic spin-labeled 46 nucleotide pre-miR-20b into ¹⁵N-labeled Rbfox RRM (amino acids 109-225 of Rbfox1) at a concentration of 0.2 mM in NMR buffer. ¹H-¹⁵N HSQC spectra were collected at 298 K on Bruker Avance 600 before and after adding 10 mM sodium hydrosulfite for reduction of the paramagnetic label.

NMR resonance assignments

For resonance assignments of the free RNA, 2D NOESY spectra (mixing time t_m of 100 ms and 300 ms), 2D TOCSY (t_m of 80 ms), ¹³C CT-HSQC and 3D ¹³C NOESY-HSQC (t_m of 300 ms) were collected on unlabeled or ¹³C, ¹⁵N labeled RNA in D₂O at 298 K to assign the non-exchangeable protons and their attached carbons. 2D NOESY spectra (mixing times $t_m = 100$ ms and 300 ms) were collected on unlabeled RNA in 90% H₂O. 10% D₂O at 279 K in order to assign the exchangeable protons. A ¹⁵N HSOC was collected on ¹⁵N labeled RNA to confirm the assignments of exchangeable protons and assign their attached nitrogens. Nearly complete assignments for H8/H6, H2, H5 and H1'-H5'/H5" were obtained for the free miR20b. For the resonance assignments of the protein in complex with the RNA, 2D ¹⁵N/¹³C HSQCs, 3D HNCACB, CBCA(CO)NH, HNCO, HN(CA)CO, HBHA(CO)NH and HCCH-TOCSY spectra were collected on ¹⁵N, ¹³C labeled protein in complex with unlabeled RNA to assign the backbone and the nonaromatic side-chains. Aromatic side chains were assigned using 2D ¹³C HSOC and 3D ¹³C NOESY-HSQC (t_m of 150 ms). A 3D ¹⁵N NOESY-HSQC (t_m of 150 ms) spectrum was also used to verify the backbone connectivity. Nearly all the assignments for backbone atoms were obtained except for the three N-terminal residues that are flexible and more than 95% of the assignments for side chain atoms were completed as well. For the assignments of the RNA in complex with the protein, 2D F1-, F2-filtered NOESYs (t_m of 100 ms and 300 ms) and 2D TOCSY (t_m of 80 ms) were collected on unlabeled RNA in complex with ¹³C, ¹⁵N labeled protein in D₂O at 298 K to assign H8/H6, H5 and H1'. In addition, ¹⁵N HSQC, ¹³C CT-HSQC and 3D ¹³C NOESY-HSQC (t_m of 300 ms) were collected on ¹³C, ¹⁵N labeled RNA in complex with unlabeled protein to assign nitrogens, carbons and the other sugar protons. Nearly complete assignments of were done for the base protons, but only 75% of assignments were obtained for sugar protons with those of A₂₂, C₃₅, C₃₇ and U₃₈ especially difficult to assign.

Structure determination

For the protein-free RNA, manually assigned NOE distance restraints derived from 3D ¹³C NOESY-HSQC and 2D NOESYs at 100 ms of mixing time were separated into three ranges based on the cross-peak intensities, strong (1.8 Å -3.5 Å), medium (1.8 Å-4.5 Å) and weak (1.8 Å-5.5 Å). Additional NOEs observed only from 2D NOESY with 300 ms of mixing time were assigned as very weak (1.8 Å-6.5 Å). Hydrogen bonds restraints for the base pairs were added based on strong NOE cross peaks to the imino protons in 2D water NOESY. Dihedral angle restraints for the conformation of sugar rings (C2'-endo or C3'-endo) were also added based on H1'-H2' cross-peak intensities in 2D TOCSY spectra. With all of the restraints above, 500 initial structures were generated in CYANA². and the 100 structures with the lowest target function were further refined in implicit solvent using the SANDER module of Amber 8.0 and the ff99 force field³. The script for the restrained simulated annealing protocol was modified from Tolbert *et al.*⁴ The NOE distance restraints for the complex could be divided into two parts, 'real' NOE derived experimentally and 'virtual' NOE predicted from the free RNA based on chemical shift similarities. The 'real' NOE list was obtained from the combination of three NOE lists: intra-protein NOEs automatically assigned from ¹⁵N and ¹³C NOESY-HSQCs obtained by CYANA; intra-RNA NOEs manually assigned from 2D F1-, F2-filtered NOESYs and 2D TOCSY spectra; and intermolecular NOEs manually assigned from 2D F1-filtered, F2-edited NOESY and 3D ¹³C F1-filtered, F3-edited NOESY-HSQC. 'Virtual' NOEs include only intra-RNA restraints for the lower stem region that retain the same conformation of free RNA, as judged from small chemical shift changes. Hydrogen

bonds and dihedral angle restraints for the RNA in complex with protein were obtained the same way as for the free RNA. Protein torsion angles were obtained by TALOS+⁵. Structure calculation for the complex was carried out the same way as for the free RNA, except that the system was heated to 1500 K instead of 600 K during Amber simulated annealing refinement.

NMR structural analysis of free miR-20b and its complex with Rbfox-RRM

Pre-miR-20b adopts a rigid terminal loop structure - Five Watson-Crick base pairs $G_{19}C_{41}$, $G_{20}C_{40}$, $U_{21}A_{39}$, $A_{22}U_{38}$ and $G_{23}C_{37}$ were initially identified through the observation of slow exchanging NH's and strong NOE cross peaks across the strand in imino-proton spectra, forming a continuous A-form helical stem. Stacking above these base pairs, we observe a non-canonical U₂₄-U₃₆ base pair, identified because the two uridines both connect to G_{23} and the imino protons of U_{24} and U_{36} show strong NOE interactions with each other and slow solvent exchange, as expected for a base pair. U₂₅ and C₃₅ were confirmed to stack above U₂₄ and U₃₆, respectively, as supported by strong sequential sugar to base and moderate base to base NOEs. The two bases can also form a base pair with a single hydrogen bond between U-O4 and C-NH4 stabilized at a pH below 5.0. At the very top of the stem, U₂₆-A₃₄ and the wobble pair U₂₇-G₃₃ were assigned from the left-over imino resonances in the 2D water NOESY, which are weak due to exposure to solvent but clearly observed. Because of the stacking of nine continuous base pairs (including U_{25} - C_{25} at pH 5.0), the A-form helix is highly regular, whereas the conformation of apical loop residues is less regular. The G₂₈ base continues stacking on top of U₂₇, while the base of C₃₀ faces inwards towards the minor groove, while the bases of G₂₉, A₃₁ and U₃₂ are splayed out with their Watson-Crick face pointing outwards to the solvent. Numerous moderate to weak NOEs between sugars of G₂₉ and C_{30} were observed, confirming their sugar rings stacking above each other, as shown in Figure 3C. In most of the structures, the sugar ring stacking conformation can be extended to A₃₁ and U₃₂, forming a backbone 'trunk' from which the bases branch out into the solvent.

The terminal loop of pre-miR-20b opens up upon binding of the Rbfox RRM - The complex of pre-miR-20b with Rbfox RRM was determined from a very large set of intermolecular NOE restraints (197, a large number for a complex of this size). Combined with the predicted restraints for the unperturbed A-form helix, based on chemical shift similarity with free pre-miR-20b, we successfully determined the structure of the complex. The RMS deviation of the heavy atoms considering the ordered parts of both RNA and protein (G₂₉-A₃₄ and Pro116-Arg194) is 0.90 Å. Overall, in the structure of the complex, the Rbfox RRM adopts the conventional $\beta 1\alpha 1\beta 2\beta 3\alpha 2\beta 4$ fold with an additional two-stranded β sheet between $\alpha 2$ and $\beta 4$, as described for its complex with ssRNA 5'-UGCAUGU-3'. The RMS deviation between C α traces of Rbfox RRM in both complexes is 1.13 Å, showing great similarity.

The loop residues of pre-miR-20b are wrapped around the protein $\beta 2\beta 3$ loop in a manner reminiscent of the U1A complex, with U_{32} and G_{33} lying across the β sheet of the RRM. Most of the intermolecular NOE interactions come from G₂₈-A₃₄ of pre-miR-20b and are similar to the complex with single stranded RNA, but they also differ in several ways. Because the most significant differences are found near the helical region, these distinctions are very likely to be real and reflect different structural context provided by the stem-loop. Instead of hydrogen bonding to the side chain of R184, the base of G_{29} favors stacking on it, as seen in 70% of the converged structures, making G₂₉ the center layer of a sandwich with F126 and R184. C₃₀ is not well restrained due to the absence of its hydrogen bond with G₂₈, as observed instead in the Fox-1-UGCAUGU complex. A₃₁ and U₃₂ are found in the same conformation as in the Fox-1-UGCAUGU complex, with similar intra- and intermolecular interactions. In contrast, even though G₃₃ maintains the stacking with F160 and adopts the same syn conformation, intra-RNA hydrogen bond G₆-2'OH to U₇-O3' are not found and its hydrogen bond to the side chain of R118 is too far to form in most of the conformers. Moreover, the two immediately flanking nucleotides of the consensus sequence $G_{29}C_{30}A_{31}U_{32}G_{33}$, G_{28} and A_{34} , demonstrate the greatest differences in binding. In the complex of Rbfox1 RRM with single-stranded RNA $(U_1G_2C_3A_4U_5G_6U_7)^6$, U_1 , equivalent to G_{28} , is orientated either parallel or perpendicular to F126 in different converged structures. In our complex, the conformation of G₂₈ cannot

be established due to very few observed NOE constraints. In the RbFox1 RRM-UGCAUGU complex, the last residue (U₇) is outside of the protein β -sheet binding surface and not constrained. In contrast, A₃₄ in the current structure has its base ring hanging above the $\beta 2\beta 3$ loop. Numerous intermolecular NOEs connect A₃₄ to the Rbfox RRM, but no intermolecular hydrogen bonds are confidently detected. The remaining intermolecular contacts occur mainly between the phosphate backbone of U₂₅-U₂₇ of pre-miR-20b and the $\beta 2\beta 3$ loop of Rbfox RRM.

Supplemental Table S1. List of human precursor miRNAs containing the Rbfox RRM target sequence GCAUG, as deduced by analysis of miRBase. TSL, refers to miRNAs with Rbfox binding sites found within the terminal stem loop sequences at or above the Dicer cleavage sites; Upper stem, binding sites are found within regions of mature miRNA sequences between the Dicer and Drosha cleavage sites; Lower stem, binding sites below Drosha cleavage sites (**Supplemental Fig. 1A**).

*: The GCAUG sequence overlaps with the Dicer or Drosha cleavage sites.

^a miR-767 has two GCAUG sequence (<u>GCAUG</u>CA<u>GCAUG</u>) within its terminal stemloop.

^b miR-297 has two UGCAUG sequence (UGCAUG UGCAUG) within its upper stem.

^c miR-4799 has two GCAUG sequences within its upper stem.

^d The lengths of the lower stems of miRNA hairpins from miRBase are variable, suggesting that some sequences may not be complete. If so, the number of miRNA hairpins containing targeting sequences that can be identified computationally would be under-estimated.

Supplemental Figure S1

(A) Secondary structure model of primary miRNA hairpin, which we arbitrarily divide into three regions for the purpose of the present analysis, as indicated in Supplemental Tables 1 and 2. (B) Alignment of miR-20b and miR-107 stem-loops from various species using sequences derived from miRBase. The mature miRNA sequences are colored as green and passenger strands are colored as yellow for guiding purpose. The conserved GCAUG sequence element targeted by the Rbfox RRM is colored in red. It is widely conserved in vertebrates for pre-miR-107, but limited only to primates in pre-miR-20b. (C) Predicted secondary structures of full-length precursor miR-20b/107 hairpins from miRbase. Mature miRNA sequences (5p and 3p) are colored in blue. (D) Truncated pre-miR-20b/107 hairpins used in EMSA binding studies.

Supplemental Figure S2

NMR analysis of the pre-miR-20b stem-loop and its interaction with the Rbfox RRM. (**A**) Overlay of the ¹⁵N HSQCs of 23 nucleotides pre-miR-20b displaying base pairing NHs in the free (black) and bound (red) states, with assignments. (**B**) Overlay of the ¹⁵N HSQCs of the 46 nucleotides pre-miR-20b displaying base pairing NHs in the free (black) and bound (red) states, with assignments. (**C**) Strips of 2D F1-filtered, F2-edited NOESY of the complex showing intermolecular NOE cross peaks to the base protons of G_{29} , A_{31} , U_{32} , G_{33} and A_{34} .

Supplemental Figure S3

(A) Sequence alignment of Rbfox family proteins in human (Fox-1, NP_061193; Fox-2, NP_001026865; Fox-3; NP_001076044), mouse (Fox-1, NP_067452), zebrafish (Fox-1, NP_001005596) and C. elegans (Fox-1, NP_001248445). (B) Sequences of the Rbfox RRM (109-194), (109-208) and (109-225) constructs used in the present study.

Supplemental Figure S4

Representative ITC binding isotherms for titration of (A) Rbfox RRM (109-194 of Rbfox1), (B) Rbfox RRM (109-208 of Rbfox1) and (C) Rbfox RRM (109-225 of Rbfox1) into pre-miR-20b. Corresponding thermodynamic parameters determined by ITC are shown as well. Two-site binding models were applied for better curve-fitting. The second weaker binding event is probably due to a weaker non-specific interaction between Rbfox RRM and pre-miR-20b.

Supplemental Figure S5

Analysis of endogenous Rbfox1 and Rbfox2 protein expression and of endogenous levels of mature miR-20b and miR-107. (**A**) Immunoblots analysis of Rbfox1 and Rbfox2 in HEK293, MCF7, NSC34, SHSY-5Y and HeLa cells. As indicated by the arrowhead, Rbfox1 is mainly expressed in the mouse motor neuron cell line NCS-34. In contrast, no expression is observed in the other cell lines analyzed. Beta-tubulin serves as a loading control. In contrast, Rbfox2 is highly expressed by HEK293 and in the neuroblastoma cell line SHSY-5Y. The asterisk indicates a possible Rbfox2 (1F) isoform. (**B**) Quantification of endogenous mature miRNAs in HeLa, HEK293, MCF7 and SHSY5Y cells. The quantification of mature miR-20b and miR-107 was done by qRT-PCR. n =3 biological replicates; average \pm s.e.m., * P < 0.05, ** P < 0.01, *** P < 0.001 (OneWay ANOVA statistical test).

Supplemental Figure S6

(A) Immunoblot analysis of Rbfox2 dowregulation by RNAi in SHSY-5Y cells. Betatubulin serves as a loading control. Cells were collected 48 hours after siRNA transfection. CTRL: cell lysate from cells transfected with scrambled siRNA. (B) Immunoblot analysis of FLAG-tagged Rbfox2 over expression. Cell lysates were prepared from MCF7 cells 48 hours after transfected with either an empty expression plasmid (CTRL) or with a plasmid expressing a FLAG-tagged Rbfox2. Actinin serves as a loading control.

Supplemental Figure S7

Analysis of endogenous Rbfox1 and Rbfox2 protein expression and the levels of mature miR-20b and 107. (A) Immunoblot analysis of Rbfox2 in MCF7 and mda-mb-231 cells. Rbfox-1A and Rbfox-1F represent two different protein isoforms. (B) Quantification of endogenous mature miR-20b and miR-107 levels in MCF7 and mda-mb-231 cells. (C) Quantification of endogenous mature miR-20b in mda-mb-231 cells after knockdown of Rbfox2 protein. (D) Effect of downregulation of Rbfox2 on mature miR-107 in mouse 4TO7 cells. (E) Immunoblot analysis of Dicer and Rbfox2 proteins in 4TO7 cells. Rbfox2-1A and Rbfox2-1F represent two different protein isoforms. Actinin serves as a loading control.

Supplemental Figure S8

Structural comparison of the Rbfox RRM (i.e. Fox-1 RRM) in complex with pre-miR-20b and single-stranded UGCAUGU6. Rbfox RRM and pre-miR-20b in the current structure are colored in green and orange; Fox-1 RRM and UGCAUGU in the reported structure are colored in white and blue, respectively. To differentiate residues and nucleotides from each complex, labels for Fox-1-UGCAUGU are provided in brackets. (A) Overall comparison of the two structures indicates high similarity. (B) Close-up view of G29 (G2) and their interactions with the protein. (C) Close-up view of G28 and C30 (U1 and C3) and their interactions with the protein. (D) Close-up view of G33 and A34 (G6 and U7) and their interactions with the protein.

Supplemental Figure S9

Long-range interactions between the C-terminal tail of Rbfox1 RRM and the lowerstem of pre-miR-20b. (**A**) Overlays of ¹H-¹⁵N HSQC spectra of ¹⁵N-labeled Rbfox1 RRM (109-225) in complex with paramagnetic spin-labeled pre-miR-20b before (red) and after (green) the reduction of the spin label introduced at position U₄₃. Some resonances from the C-terminal tail of Rbfox1 RRM, which are broadened by the paramagnetic spin label of pre-miR-20b, are annotated. (**B**) Intensity ratios of NH cross-peaks from Rbfox1 RRM (109-225) in complex with pre-miR-20b, between paramagnetic and diamagnetic forms. Residues from the $\beta_2\beta_3$ loop (around E152) and the C-terminal region (V195-V215) show significant depressions, indicating longrange contacts between the bottom part of the RNA and the protein. (C) Cartoon representation showing how the highly conserved C-terminal tail of RRM can reach the bottom part of the stem-loop to provide additional contacts that are obviously not possible with single stranded RNA.

7. Lewis, B. P., Burge, C. B. & Bartel, D. P. Conserved seed pairing, often flanked by adenosines, indicates that thousands of human genes are microRNA targets. *Cell* **120**, 15-20 (2005).

8. Krek, A. *et. al* Combinatorial microRNA target predictions. *Nat. Genetics* **37**, 495-500 (2005).

9. Zhou, W., Shi, G., Zhang, Q., Wu, Q., Li, B. & Zhang, Z. MicroRNA-20b promotes cell growth of breast cancer cells partly via targeting phosphatase and tensin homologue (PTEN). *Cell & Bioscience* **4**, 62-72 (2014).

10. Zaman, M.S., *et al.* Inhibition of PTEN gene expression by oncogenic miR-23b-3p in renal cancer. *PLoS One*, 7(11), e50203 (2012).

11. Huse, J. T. *et al.* The PTEN-regulating microRNA miR-26a is amplified in high-grade glioma and facilitates gliomagenesis *in vivo*. *Genes Dev.* **23**, 1327–1337 (2009).

12. Wu, W., Yang, J., Feng, X., Wang, H., Ye, S., Yang, P., Tan, W., Wei, G. & Zhou, Y. MicroRNA-32 (miR-32) regulates phosphatase and tensin homologue (PTEN) expression and promotes growth, migration, and invasion in colorectal carcinoma cells. *Mol. Cancer* **12**:30 (2013).

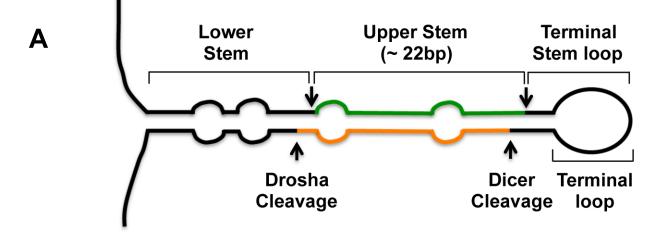

13. Soubani, O., Ali, A.S., Logna, F., Ali, S., Philip, P.A. & Sarkar, F.H. Re-expression of miR-200 by novel approaches regulates the expression of PTEN and MT1-MMP in pancreatic cancer. *Carcinogenesis* **33**, 1563-1571 (2012).

14. Cai, J., *et al.* miR-205 targets PTEN and PHLPP2 to augment AKT signaling and drive malignant phenotypes in non-small cell lung cancer. *Cancer Res.* **73**, 5402-5415 (2013).

15. Chun-Zhi, Z. *et al.* MicroRNA-221 and microRNA-222 regulate gastric carcinoma cell proliferation and radioresistance by targeting PTEN. *BMC Cancer* **10**, 367-376 (2010).

16. Poliseno, L. *et al.* Identification of the miR-106b-25 microRNA cluster as a protooncogenic PTEN-targeting intron that cooperates with its host gene MCM7 in transformation, *Sci. Signal.* **3**, ra29 (2010).

17. Small, E. M. *et al.* Regulation of PI3-kinase/Akt signaling by muscle-enriched microRNA-486. *Proc. Natl Acad. Sci. USA* **107**, 4218–4223 (2010).
