

**Supplementary Figure 1 | PL spectra at selected temperatures.** Steady-state PL spectra at selected temperatures for (a) FAPbI<sub>3</sub>, (b) FAPbBr<sub>3</sub>, (c) MAPbI<sub>3</sub> and (d) MAPbBr<sub>3</sub>. The y-direction represents the normalised PL intensity.

**Supplementary Figure 2 | Temperature variation of PL linewidth as a multiple of thermal energy.** Temperature dependence of the full width at half maximum (FWHM, plotted as black squares) of the steady-state PL spectra expressed as a multiple of the thermal energy  $k_B T$ , for (a) FAPbI<sub>3</sub>, (b) FAPbBr<sub>3</sub>, (c) MAPbI<sub>3</sub> and (d) MAPbBr<sub>3</sub>.

**Supplementary Figure 3 | Carrier energy distribution from PL tails.** Steady-state PL spectra at temperatures ( $T$ ) for an FAPbI<sub>3</sub> thin film, plotted as red crosses. The high-energy tails of the band edge PL can be approximated by the dashed red lines representing the functional form  $I(E) \propto \exp[-(E - E_g)/k_B T_c]$ , which describes the PL lineshape expected from thermalized charge carriers of temperature  $T_c$  following a Boltzmann energy distribution<sup>1</sup>.  $I$  is the PL intensity,  $E$  is the PL energy and  $E_g$  is the bandgap energy. The solid black line indicates the position on the curves at which the FWHM is measured, which lies above the high-energy tail of the band edge PL. For the shown dashed red lines, the carrier temperature  $T_c$  was set as the sample temperature  $T$ . However, slightly shallower tails (indicating  $T_c$  somewhat higher than  $T$ ) are actually observed. One reason for this discrepancy may lie in the strongly non-resonant excitation at 3.1 eV which leads to an initial thermalized “hot” charge-carrier density that subsequently cools to the lattice temperature<sup>2,3</sup>. Since the PL curves shown represent an average over the charge-carrier temperature during the lifetime of charge-carriers, a temperature slightly elevated above the lattice temperature may be found. However, the overall line shape is also strongly governed by electron-phonon coupling, as described in the main text, whose effects will influence the spectral shape also in the high-energy tail.

**Supplementary Figure 4 | Phonon dispersion and population relations from *ab initio* calculations.** The calculated phonon dispersion relation for MAPbI<sub>3</sub> is shown in (a), with the acoustic modes (bottom) and the polar optical modes (top) highlighted in orange. Here we see that the frequency of the acoustic modes is always smaller than 2.5 meV, while the polar optical modes are centred on 13 meV. On the right, the phonon population according to the Bose-Einstein function,  $N(T)$ , is plotted in red as a function of temperature for (b) the acoustic modes and (c) the polar optical modes. The Bose-Einstein phonon population is offset vertically by  $+1/2$  to allow direct comparison with linear approximations to the phonon population, which are plotted as dotted black lines. The linear temperature dependence used in Eqn. 1 in the main text for the linewidth broadening due to acoustic phonons is therefore very accurate in the case of MAPbI<sub>3</sub> for all temperatures above 10 K, while the Bose-Einstein function is necessary to model the broadening due to optical phonons.

**Supplementary Table 1 | Linewidth parameters for perovskites and inorganic semiconductors.** Collated values of linewidth parameters for inorganic semiconductors reported by other experimental studies, along with those obtained from our data. We use the FWHM definition of linewidth, but some papers, indicated by an asterisk (\*) in the materials column, define it as the HWHM (Half Width at Half Maximum); we multiply by two the  $\Gamma_0$ ,  $\gamma_{ac}$ ,  $\gamma_{LO}$  and  $\gamma_{imp}$  values from these papers. Blank cells indicate parameters which were not considered in a paper. When a parameter used in a fit was fixed, that value is underlined in the table. Materials were studied in the bulk, except for those at the bottom of the table, which were studied as quantum wells (indicated by  $^{\S}$ ), or epilayers ( $^{\ddagger}$ ).

Material	Technique	Source	$\Gamma_0$ (meV)	$\gamma_{ac}$ ( $\mu\text{eV K}^{-1}$ )	$\gamma_{LO}$ (meV)	$E_{LO}$ (meV)	$\gamma_{imp}$ (meV)	$E_b$ (meV)

**Supplementary Table 2 | Calculated electrical parameters.** Calculated Born effective charges ( $Z^*$ ), high-frequency and static dielectric constants ( $\epsilon^\infty$  and  $\epsilon^0$  respectively) of MAPbI<sub>3</sub> and MAPbBr<sub>3</sub> in the orthorhombic phase. We report the isotropic average of the tensors, and we compare the dielectric constants to experiment.

	$Z^*$				$\epsilon$			
	Pb	I/Br	C	N	$\epsilon^\infty$	$\epsilon_{\text{exp}}^\infty$	$\epsilon^0$	$\epsilon_{\text{exp}}^0$
MAPbI <sub>3</sub>	+4.42	-1.88	+0.03	-0.95	5.86	6.5 <sup>17</sup>	25.3	30.5 <sup>18</sup>
MAPbBr <sub>3</sub>	+4.11	-1.78	+0.09	-0.80	4.71	4.8 <sup>19</sup>	23.9	26.2 <sup>18</sup>

**Supplementary Note 1 | Details of first-principles calculations.** The GW calculations for the quasiparticle energies were performed as described previously<sup>20</sup>. The SS-GW eigenvalues were interpolated using Wannier functions starting from a 4×4×4 grid. This gives effective masses in very good agreement with the experiment, which is crucial for electron-phonon calculations. In fact, the electron-phonon self-energy at the band edges is very sensitive to the curvature of the bands.

The lattice dynamical properties of MAPbI<sub>3</sub> were calculated according to a previously published procedure<sup>21</sup>. All calculations were performed for the low-temperature orthorhombic structure of MAPbI<sub>3</sub>, since the vibrational frequencies are relatively insensitive to the structure<sup>21</sup>, and the measured PL broadening does not change across the orthorhombic/tetragonal phase transition. In the case of MAPbBr<sub>3</sub> the vibrational properties were calculated for the orthorhombic structure, starting from the lattice parameters and atomic coordinates given by Swainson *et al.*<sup>22</sup>.

In order to evaluate the electron-phonon self-energy we calculated the electron-phonon matrix elements using the *ab initio* Fröhlich vertex<sup>23</sup> in its simplified form, as given in Supplementary Equation 1. The calculated Born effective charges and dielectric constants are reported in Supplementary Table 2. Additionally, we accounted for the quasiparticle renormalization of the electron lifetime by calculating the factor  $Z$ , which corresponds to an improved solution of the Dyson equation<sup>24,25</sup>.

**Supplementary Equation 1 | *Ab initio* Fröhlich vertex.** Here  $\mathbf{Z}^* = Z_{\alpha\beta}^*$  is the Born effective charge tensor,  $\epsilon_{\infty} = \epsilon_{\infty,\alpha\beta}$  is the high-frequency dielectric tensor,  $\mathbf{e}_{\kappa\nu}(\mathbf{q})$  is a vibrational eigenmode,  $\mathbf{G}$  represents a reciprocal lattice vector, and  $M_{\kappa}$  is the mass of atom  $\kappa$ .

$$g_{mn}^{\nu}(\mathbf{q}) = i \frac{4\pi e^2}{\Omega} \sum_{\kappa} \left( \frac{\hbar}{2M_{\kappa}\omega_{\mathbf{q}\nu}} \right)^{\frac{1}{2}} \sum_{\mathbf{G} \neq -\mathbf{q}} \frac{(\mathbf{q}+\mathbf{G}) \cdot \mathbf{Z}_{\kappa}^* \cdot \mathbf{e}_{\kappa\nu}(\mathbf{q})}{(\mathbf{q}+\mathbf{G}) \cdot \epsilon^{\infty} \cdot (\mathbf{q}+\mathbf{G})} \delta_{mn} \quad (1)$$
