Absolute Metabolite profiling

Targeted metabolomics analysis of WT KRAS and G12C KRAS isoforms in NSCLC isogenic cell lines and their correspondent xenograft tumor samples was performed using the Biocrates AbsoluteIDQTM p180 kit (Biocrates Life Science AG, Innskruck, Austria). This validated targeted assay allows for simultaneous detection and quantification of metabolites in biological samples in a high-throughput manner. The metabolite extracts were processed following the instructions by the manufacturer and analyzed on a triple-quadropole mass spectrometer (AB SCIEX triple-quad 5500) operating in the multiple reaction monitoring (MRM-MS) mode. The assay is based on PITC (phenylisothiocyanate)-derivatization in the presence of internal standards for the analysis of aminoacids and biogenic amines resolved and quantified by liquid chromatography- tandem mass spectrometry (LC-MS/MS) using scheduled MRMs. Subsequent flow injection analysis tandem mass spectrometry (FIA-MS/MS) was performed to analyze acylcarnitines, glycerophospholipids, hexose. MRM detection was used for quantification applying spectra parsing algorithm integrated into the MetIQ software (Biocrates Life Science AG, Innskruck, Austria). Concentrations were calculated and evaluated by comparing measured analytes in a defined extracted ion count section to those of specific labeled internal standards or non-labeled ones, provided by the kit. Metabolite concentration were normalized based on cell numbers and tumor weight using cell normalization and tissue factor tools implemented into MetIDQ-boron software (Biocrates). The measurements are made in a 96-well format. Seven calibration standards, five quality control samples, three zero samples (methanol) and one blank (solvents) are integrated into the plate. The limit of detection for the individual metabolites is set three times the value of the “zero samples”. The average coefficient of variation of the metabolites among the biological replicates was 30%. This variation is the sum of biological and technical variation. Based on the five quality controls (QCs) included in the mass spectrometric analysis to monitor the instrumental performances and evaluate the quality of the

data, the CV was below 15% (technical variation). For glycerophospholipids, the precise position of the double bonds and the distribution of the carbon atoms in different fatty acid side chains cannot be determined with this technology. Lipid side-chain composition is abbreviated as Cx:y, where x denotes the number of carbons in the side chain and y the number of double bonds. The nature of fatty acids linkage is expressed as aa for diacyl or ae for acyl-alkyl. For example, PCaaC32:1 denotes diacyl-phosphatidylcholine with 32 carbons in the two fatty acids side chains and a single double bond in one of them. The list of all the measurable metabolites is provided in **supplementary table S5**.

Supplementary Figure 1. Tumor growth of G12C KRAS or WT KRAS cells in immunodeficient mice. Mice were inoculated subcutaneously with 200 uL of cell suspension containing 5×10^6 WT or G12C KRAS cells. The growing tumor masses were measured with a Vernier caliper, and the tumor weights ($1\text{mm}^3 = 1\text{mg}$) were calculated with the formula: length x (width)²/2. The tumor weight on day n was expressed as relative tumor weight (RTW) according to the following formula: RTW = TW_n/TW₀, where TW_n is the tumor volume on day n and TW₀ is the volume on the day of the first measurement.
