\* Mean (standard deviation), <sup>a</sup> Variance analysis for continuous data, <sup>b</sup> Chi-square-tests for categorical data. The quartiles of serum indirect bilirubin levels were calculated by sex respectively. The cutoff values of serum indirect bilirubin quartiles were <8.0, 8.0–10.6, 10.6–13.6, and >=13.6 umol/L for males and <6.6, 6.6–8.6, 8.6–11.2, and >=11.2 umol/L for females respectively.

Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; BMI, body mass index; ALP, alkaline phosphatase; HDL, high-density lipoprotein; LDL, low-density lipoprotein.

**Supplementary table S 4. Baseline characteristics of study participants according to serum total-bilirubin levels quartiles**

\* Mean (standard deviation), <sup>a</sup> Variance analysis for continuous data, <sup>b</sup> Chi-square-tests for categorical data. The quartiles of serum total bilirubin levels were calculated by sex respectively. The cutoff values of serum total bilirubin quartiles were <12.0, 12.0–15.2, 115.2–19.0, and >=19.0 umol/L in males and <9.9, 9.9–12.0, 12.0–15.3, and >=15.3 umol/L in females respectively.

Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; BMI, body mass index; ALP, alkaline phosphatase; HDL, high-density lipoprotein; LDL, low-density lipoprotein

<sup>a</sup> model 1: Adjusted for the age, plus education level, current smoking status, current alcohol drinking status and physical activity.

<sup>b</sup> model 2: Adjusted for the variables in the model 1 plus coronary heart disease, diabetes, hypertension disease, tumor history and lipid lowering agent.

<sup>c</sup> model 3: Furthered adjusted for the same set of variables in the model 2 plus waist circumference, body mass index, glucose, high-density lipoprotein, total cholesterol, triglyceride and uric acid.

The ORs and 95% CIs were calculated by unconditional logistic regression after adjusting for above potential confounders and the cutoff values of bilirubin quartiles for males were direct bilirubin (<3.7, 3.7–4.5, 4.5–5.6, and >=5.6 umol/L), indirect bilirubin (<8.0, 8.0–10.6, 10.6–13.6, and >=13.6 umol/L), and total bilirubin (<12.0, 12.0–15.2, 15.2–19.0, and >=19.0 umol/L) respectively.

<sup>a</sup> model 1: Adjusted for the age, plus education level, current smoking status, current alcohol drinking status and physical activity.

<sup>b</sup> model 2: Adjusted for the variables in the model 1 plus coronary heart disease, diabetes, hypertension disease, tumor history and lipid lowering agent.

<sup>c</sup> model 3: Furthered adjusted for the same set of variables in the model 2 plus waist circumference, body mass index, glucose, high-density lipoprotein, total cholesterol, triglyceride and uric acid.

The *ORs* and 95% *CIs* were calculated by unconditional logistic regression after adjusting for above potential confounders. The quartiles of bilirubin levels were calculated by sex respectively. The cutoff values of bilirubin quartiles for males were direct bilirubin (<3.7, 3.7–4.5, 4.5–5.6, and >=5.6 umol/L), indirect bilirubin (<8.0, 8.0–10.6, 10.6–13.6, and >=13.6 umol/L), and total bilirubin (<12.0, 12.0–15.2, 15.2–19.0, and >=19.0 umol/L) respectively, and for females were direct bilirubin (<2.9, 2.9–3.6, 3.6–4.5, and >=4.5 umol/L), indirect bilirubin (<6.6, 6.6–8.6, 8.6–11.2, and >=11.2 umol/L), and total bilirubin (<9.9, 9.9–12.0, 12.0–15.3, and >=15.3 umol/L) respectively.

**Supplementary table S 8. Odds ratios (95% confidence intervals) for incident NAFLD by serum bilirubin levels quartiles among individuals with BMI >=24 kg/m<sup>2</sup> (n=3218)**

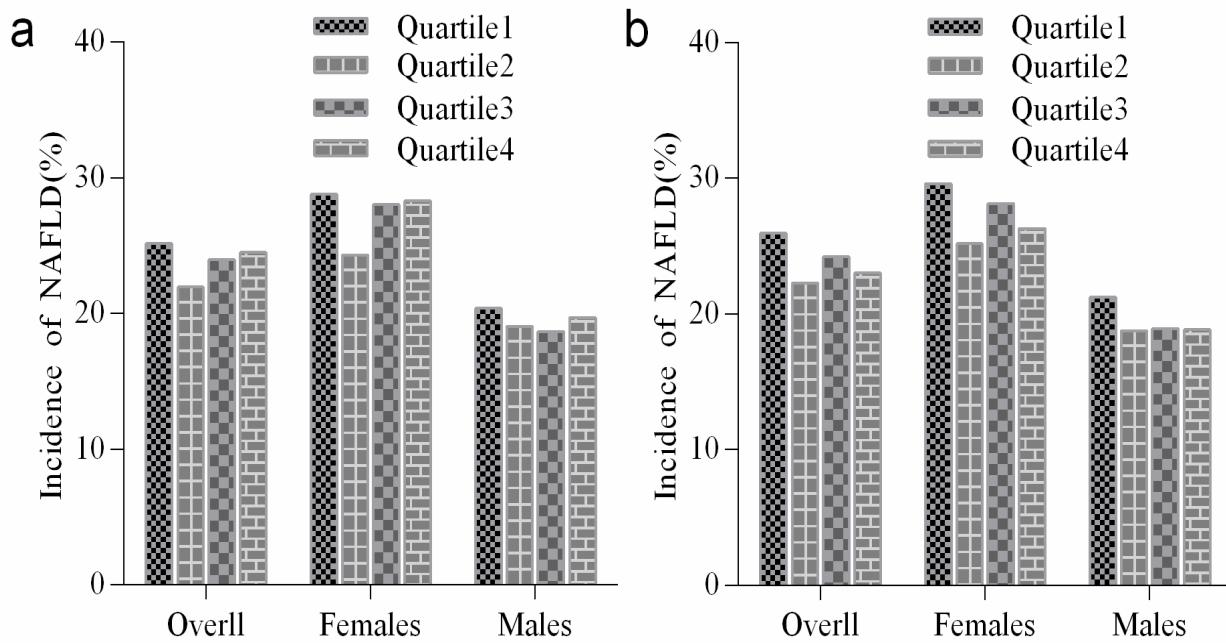

| Sample size (%)                   | Incident cases (%) | Univariate model | Age-and sex-adjusted | Multivariable model  |                      |                      |
