Supplmentary Figure 2. Beeswarm plots showing methylation beta-values for the top ten differentially methylated loci (ranked by uncorrected *p*-value) identified when comparing high-risk individuals who remained well (WL) to those who developed either bipolar disorder (BD) or major depressive disorder (MDD). For illustration purposes, beta-values are plotted separately according to future diagnosis; all analyses were, however, carried out using a combined "ill later (MDD and BD)" group.
