Synthesis of  $[\text{Co}^{\text{III}}(\text{dmgH})_2(\text{py})_2]\text{NO}_3$  (**8**). Cobalt nitrate hexahydrate (1.18 g, 4.05 mmol) and dimethylgloxime (0.99 g, 8.53 mmol) were placed in a large test tube with a stir bar, and then dissolved with a minimum volume of boiling absolute ethanol. Pyridine (0.80 mL, 9.93 mmol) dissolved in a minimum volume of absolute ethanol was added to the reaction mixture with vigorous stirring. Heating and stirring was continued for 30 minutes. After the heat was turned off, the solution was allowed to cool while

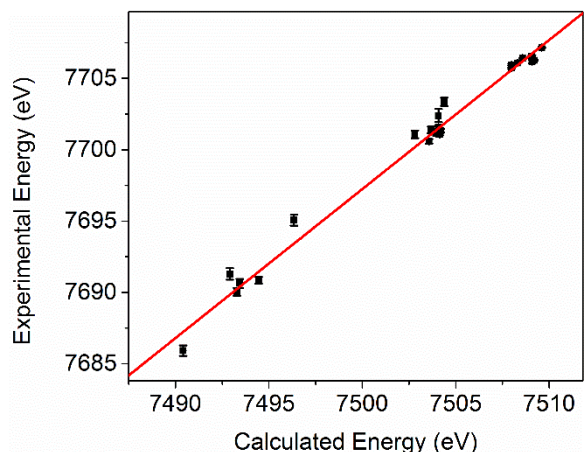

a stream of air was bubbled into the solution for one hour. The air stream was then removed and the solution was allowed to sit at room temperatures for an additional hour while the precipitate formed. **Figure S2.** Correlation of calculated vs. experimental V2C X-ray emission energies for low-spin octahedral cobalt(III) complexes. The linear fit gives a slope of  $1.045 \pm 0.029$ , and an intercept of  $-138.2 \pm 220.7$ . The width-modulated calculated spectra (hwhm: 2.0 eV) were curve-fitted with three to four pseudo-Voigt functions having a fixed 50:50 proportion of Gaussian and Lorentzian character in order to determine the center energies of  $K\beta_{2,5}$  and  $K\beta''$  peaks of the calculated spectra. The center energies of the  $K\beta_{2,5}$  and  $K\beta''$  peaks of the experimental spectra were obtained following procedures described in the experimental section of the text. Error bars of both experimental and calculated data shown in the figure represent the standard deviation.

**Figure S3.** Correlation of calculated vs. experimental V2C areas for low-spin octahedral cobalt(III) complexes. The linear fit has been forced through the origin (intercept = 0), and the slope is  $(5.4 \pm 0.1) \times 10^{-4}$ . Error bars represent the standard deviation. The calculated V2C area is taken from the calculated oscillator strength that encompasses the electric dipole, magnetic dipole, and electric quadrupole contributions.

<sup>a</sup> Weighted Sum of Squared Residuals (WSSR), also called chi-square, is defined as  $\chi^2(\mathbf{a}) = \sum_{i=1}^N \left[ \frac{y_i - y(x_i; \mathbf{a})}{\sigma_i} \right]^2$ , where  $\sigma$  is the standard deviation. <sup>b</sup> This high-energy peak above the K $\beta_{2,5}$  feature is not included in the V2C total area. <sup>c</sup> Uncertainties associated with the energy and area of each peak are determined using the Fityk program with a pseudo-VoigtA function; for all fits, the shape parameter is fixed to 0.5, and the active range is set to 7680 – 7725 eV. V2C XES spectra of cobalt complexes **1** to **6** are well fitted by four or five peak. For complexes **7** to **10**, while a four-peak fit model improves the goodness-of-fit with a significantly reduced WSSR value compared to a three-peak fit, one of the individual peaks (~7708 eV) has a very large uncertainty in peak area. We therefore consider the three-peak fit as the best curve-fitting model.
