Supplementary Fig 1. The relationship between GC content and COI distance across genera. Mean nearest neighbour distance (% K2P) between congeneric species at COI plotted against mean GC content (%) in the 123 genera of marine molluscs. The regression was significant ($P < 0.001$; $R^2 = 0.167$).

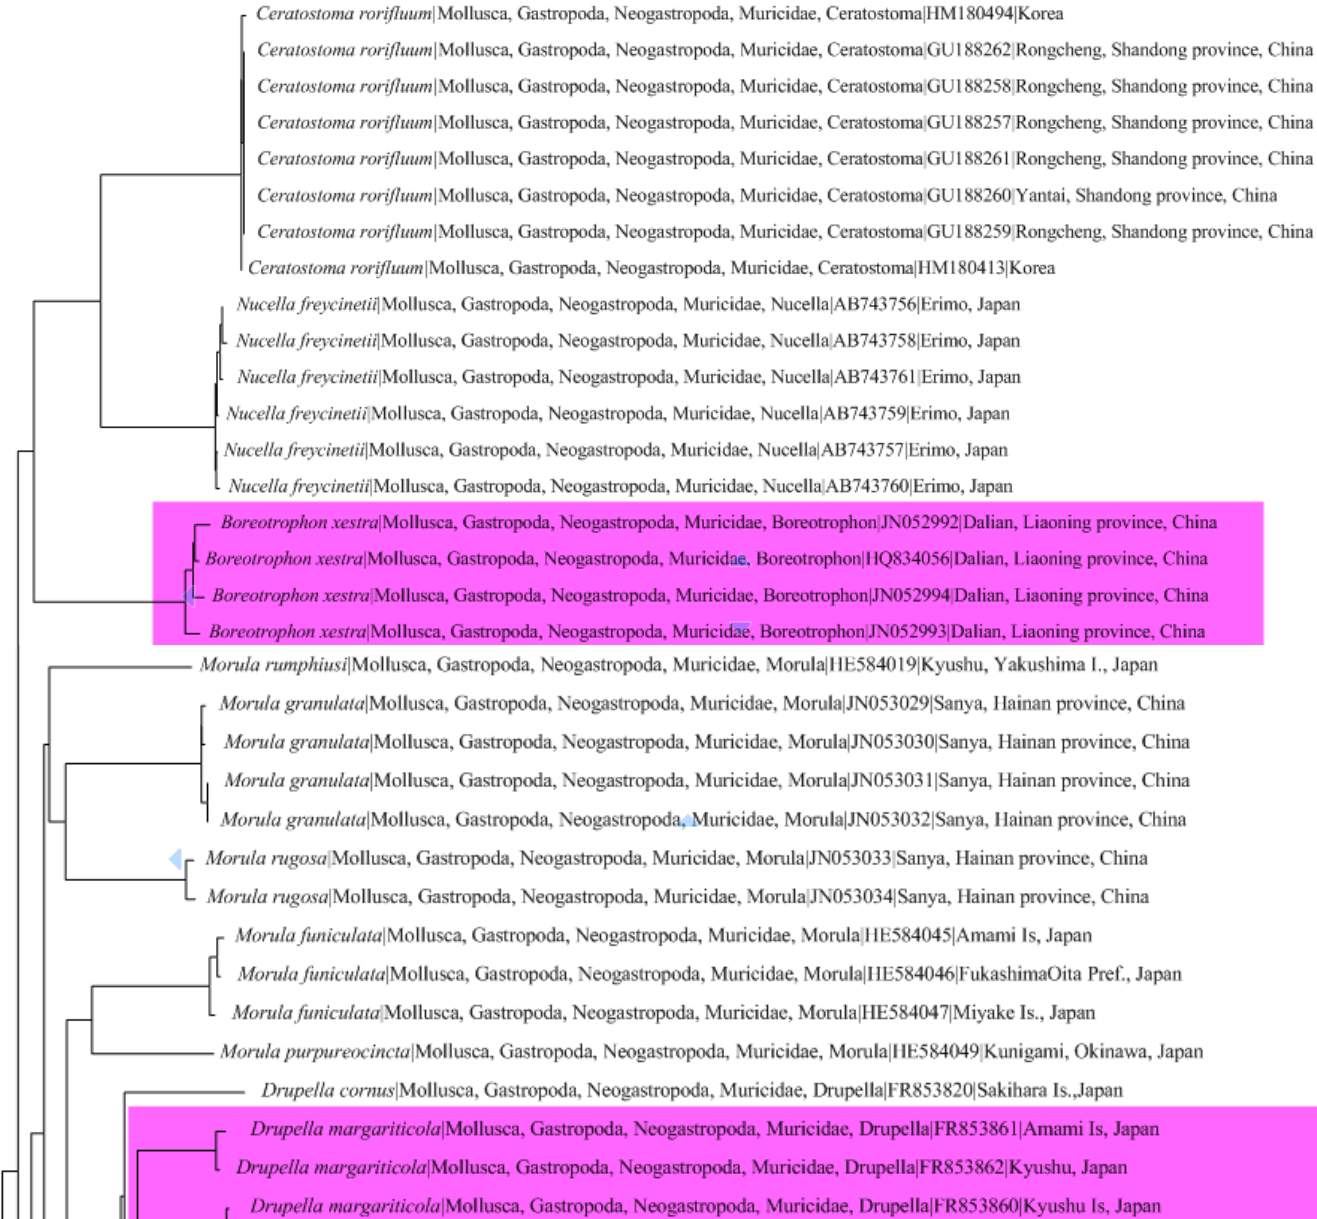

Supplementary Fig 2. Histogram of threshold optimization method reporting the frequencies of false-positive error (no conspecific matches within threshold but conspecific samples available) and false-negative error (more than one species recorded within threshold) identifications across thresholds values from 0.01 to 0.1.

Supplementary Fig 3. Density plot of genetic distances generated by the function 'localMinima' in SPIDER package corresponding to the transition between intra- and interspecific distances. The minimum of a density plot of genetic distances is highlighted in grey.

Supplementary Fig 4 Neighbour-Joining (NJ) tree of 2801 COI barcodes based on K2P model (performed on the BOLD database). The highlighted cluster in magenta and yellow indicate species with a high cryptic diversity and species formed paraphyly clusters, respectively. The framed clusters indicate the species characterized by haplotype sharing.

A phylogenetic tree showing the relationships between several species of bivalves. The tree is rooted on the left and branches out to the right. The species names and their associated taxonomic information and collection details are listed to the right of the branches. The tree is divided into several major clades, some of which are highlighted with a pink background. The clades include Mercenaria, Periglypta, Globivenus, and Chemnitzia. The Mercenaria clade is the largest and is highlighted in pink. The Periglypta clade is also highlighted in pink. The Globivenus clade is not highlighted. The Chemnitzia clade is not highlighted.
