

Supplementary Information for:
**A proteinaceous organic matrix regulates carbonate mineral production
in the marine teleost intestine**

Kevin L. Schauer, Christophe M. R. LeMoine, Adrian Pelin, Nicolas Corradi, Wesley C. Warren,
and Martin Grosell

Supplementary Methods

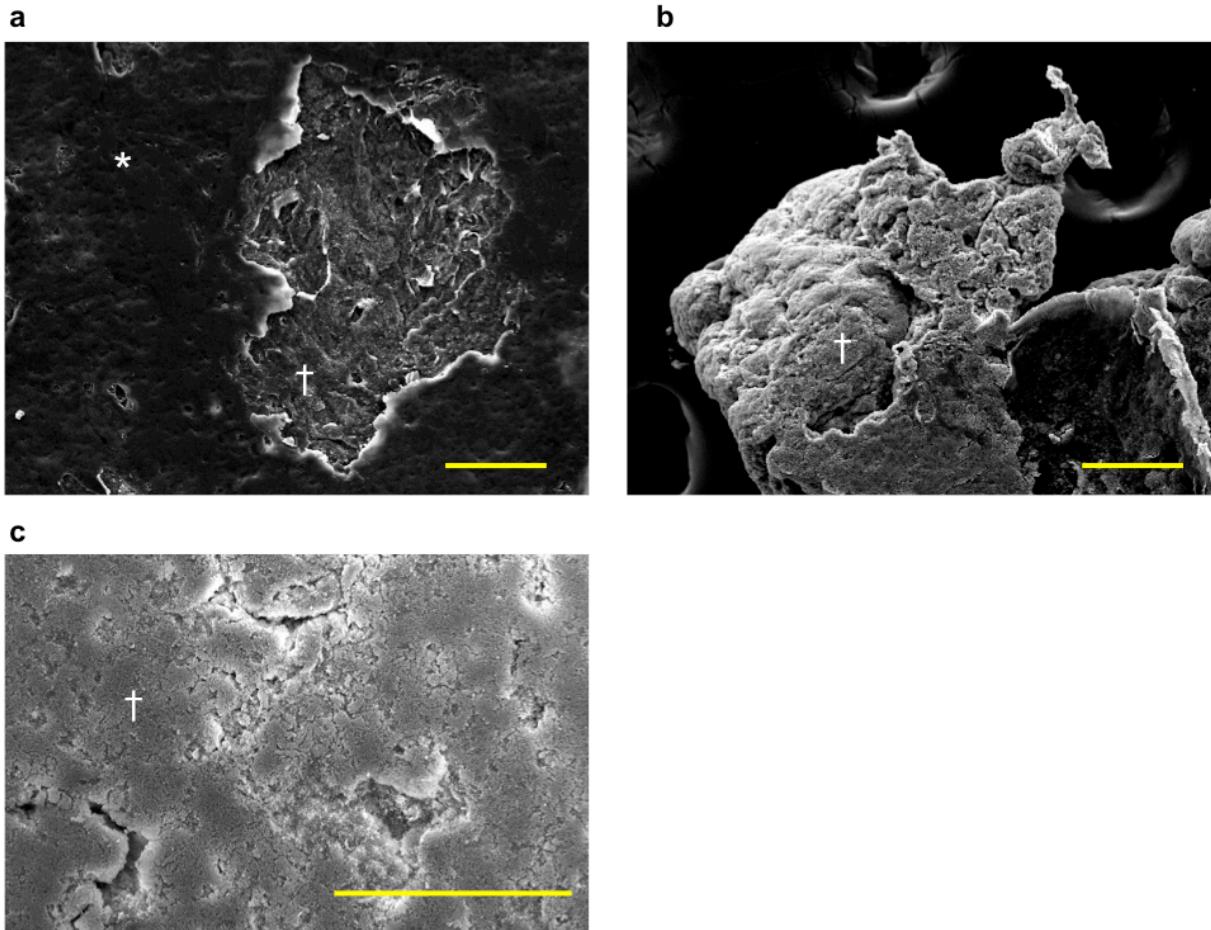

Transcriptomics

Flash frozen tissues (Supplementary Table S1) were pulverised under liquid nitrogen, homogenized in Trizol (ThermoFisher Scientific) and RNA was extracted following the acid-phenol chloroform extraction protocol. The transcriptome of each category of tissues was generated by subjecting pooled RNA samples to Illumina sequencing at the Washington University Genome Institute (St Louis, MO). De novo transcriptome assembly was initiated using Velvet¹ (v1.2.07) for a k-mer value of 93 for all samples with parameters chosen by VelvetOptimiser (v2.2.0; <http://www.vicbioinformatics.com/software.velvetoptimiser.shtml>). For every sample, the assembly was processed by the Oases add-on as per author's instructions². Assembled transcripts for all samples were individually imported into the Blast2GO pipeline³ and annotated with GO terms as well as InterProScan domains⁴. Further, from each library we subtracted transcripts present in other libraries to generate a list of loci unique to each set of sequenced tissues. The GO term enrichment analysis of these unique libraries is represented as percent relative abundance per tissue set, computed from total count numbers for each category represented (Supplementary Fig. S2).

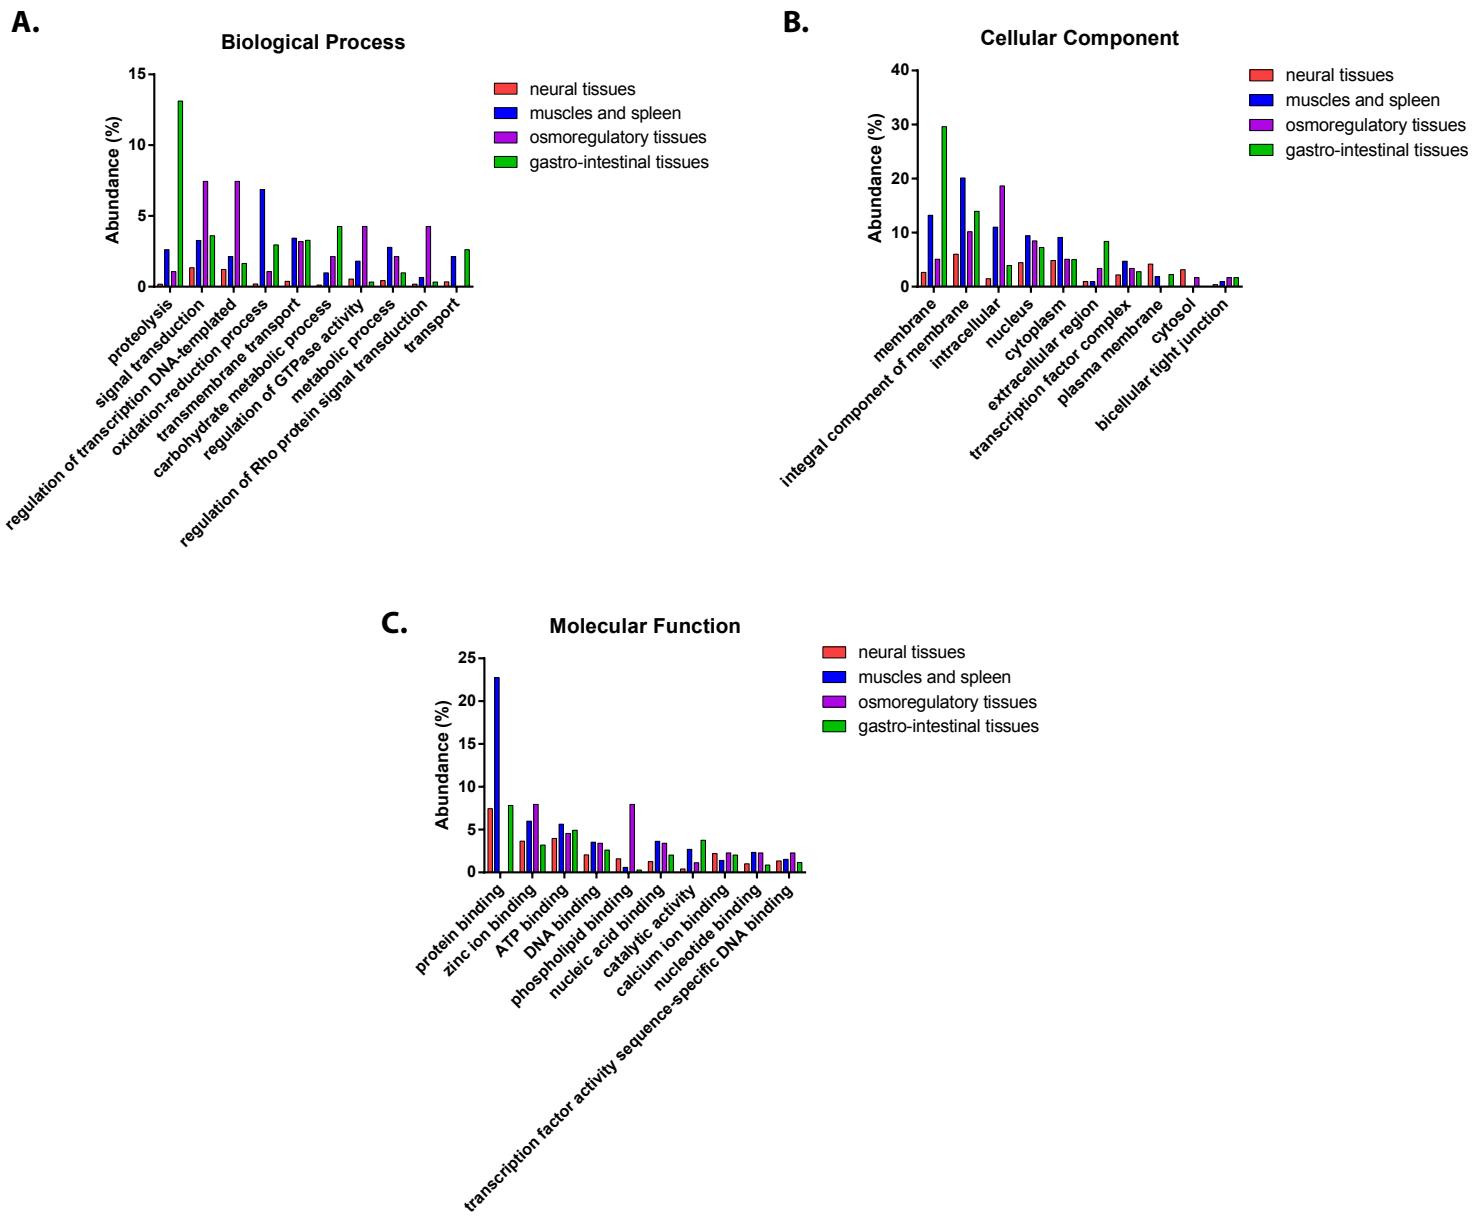

pH-stat experiments

Buffers identical to those used in the micro-modified CA assay were used in the pH-stat experiments, but thymol blue was omitted. Bicarbonate buffer (675 µl) was added to a 2 ml,

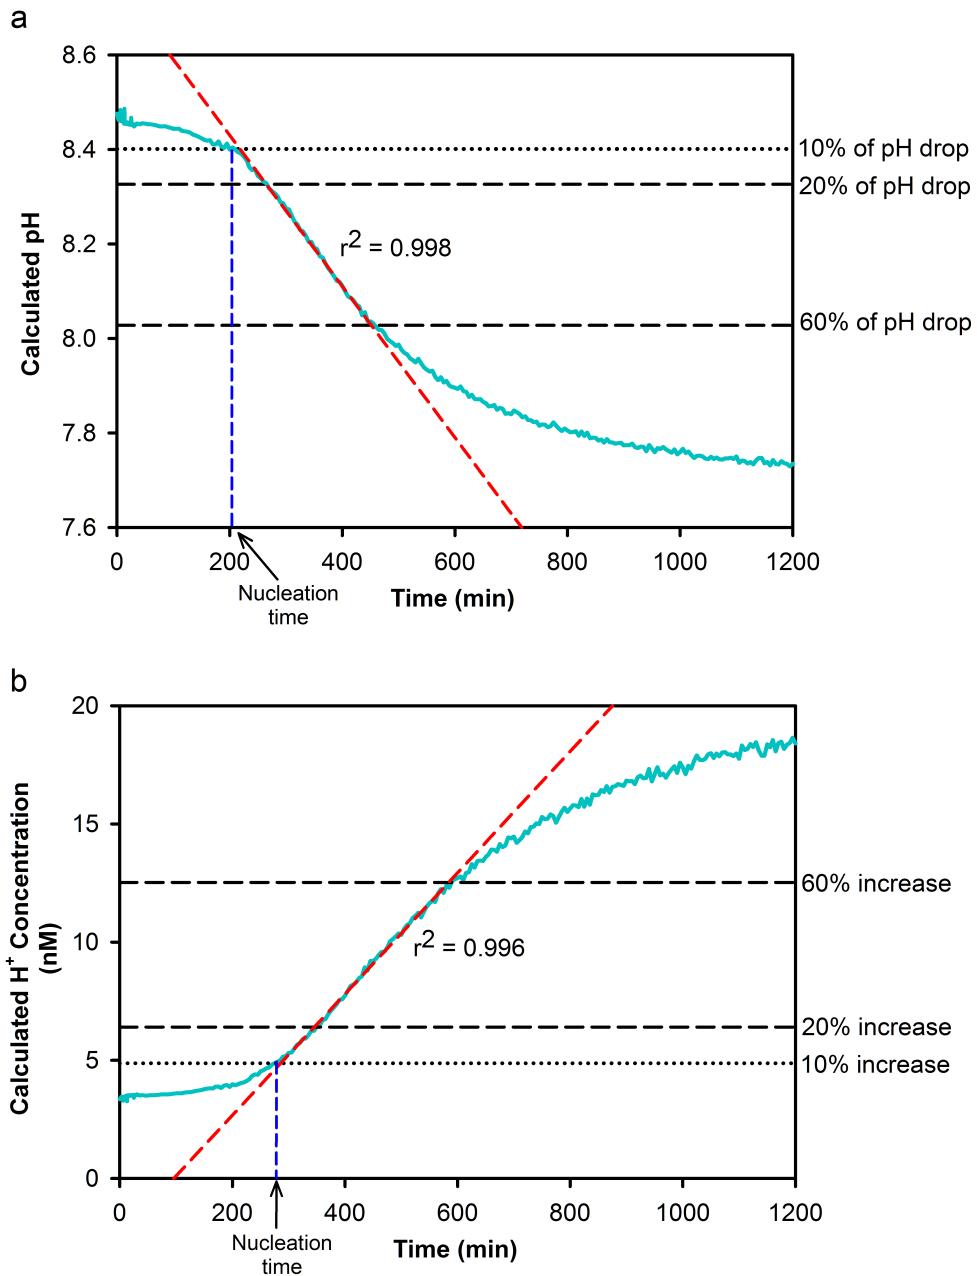

water-jacketed vessel maintained at 25°C, followed by matrix samples diluted in TBS (150 µl), and finally 675 µl of calcium buffer. Samples were vigorously stirred throughout the duration of the experiment by a magnetic stir bar. The pH of the solution was measured by a PHC4000.8 electrode (Radiometer) attached to a TIM 854 or 856 automatic titrator, which delivered 0.2N NaOH (prepared from a standardized stock solution) via a microburette tip inserted into the solution. Titrant was added at the rate necessary to maintain a constant pH of 8.6. During the beginning of the experiment, NaOH was added rapidly in order to bring the pH up to 8.6, as the TBS which contained the matrix had a pH of 7.6. Once the pH of 8.6 was achieved by the initial base addition, the pH of the solution would slowly drift upwards until calcification began, which would in turn cause the pH to begin dropping. During the period of increasing pH, the microburette tip was removed from the solution in order to prevent it from being clogged by precipitation of CaCO₃. The pH of the solution as well as the addition of titrant was recorded every 20 s by a personal computer running Titramaster software (v5.1.0; Radiometer). The reaction was allowed to proceed until base addition had not occurred for a minimum of 5 minutes. Nucleation time was determined to be the time of max pH, due to the reasons described above (Supplementary Fig. S5). Max calcification rate was the max rate of titrant addition averaged over a 20s period (excluding the initial base addition to achieve a pH of 8.6; Supplementary Fig. S4). Nucleation times and calcification rates were normalized and compared to control experiments that contained no protein (TBS only) by one-way ANOVA and multiple comparison analyses by the Holm-Sidak method.

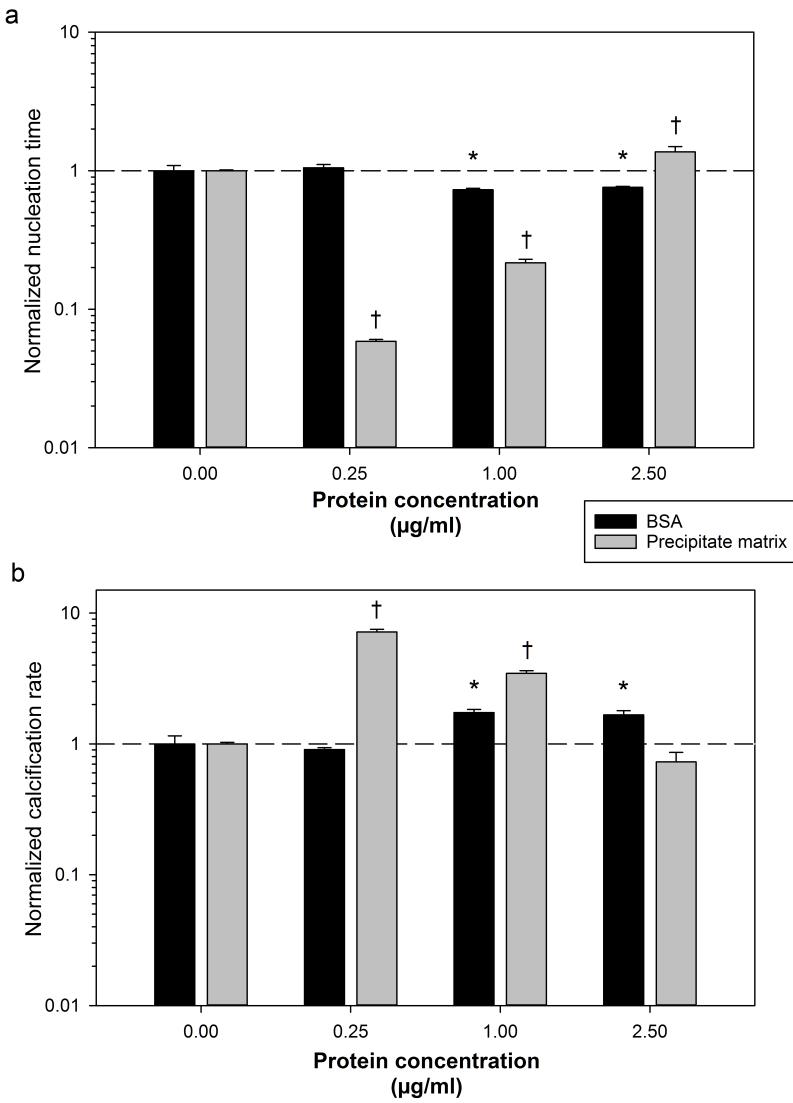

Supplementary Figure S1: Scanning electron microscopy (SEM) images of intestinal CaCO₃ precipitates. **(a)** Unpurified precipitates, **(b)** gentle purification procedure purified precipitates collected directly from the intestines of Gulf toadfish (*Opsanus beta*), and **(c)** precipitates collected from the tank bottom and purified using the stringent purification method. * Mucus coating; † exposed CaCO₃. Scale bar = 100 μm .

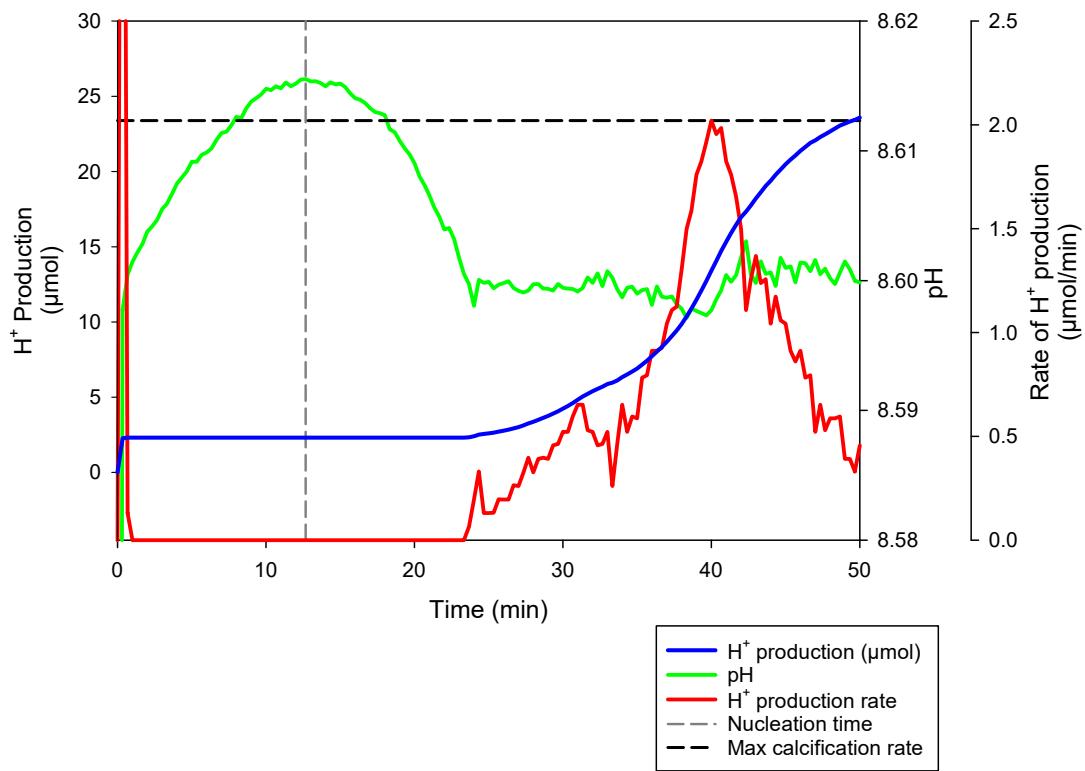

Supplemental Figure S2: Gene ontologies of unique transcripts in the toadfish functional transcriptome libraries. Unique transcripts within neural tissues (red), muscles (blue), osmoregulatory tissues (purple) and gastro-intestinal tissues (green) were annotated and gene ontology assigned in Blast2GO (see Methods). Within each library, the relative abundance of the most represented GO term was computed for **(A)** biological processes, **(B)** cellular components and **(C)** molecular function.

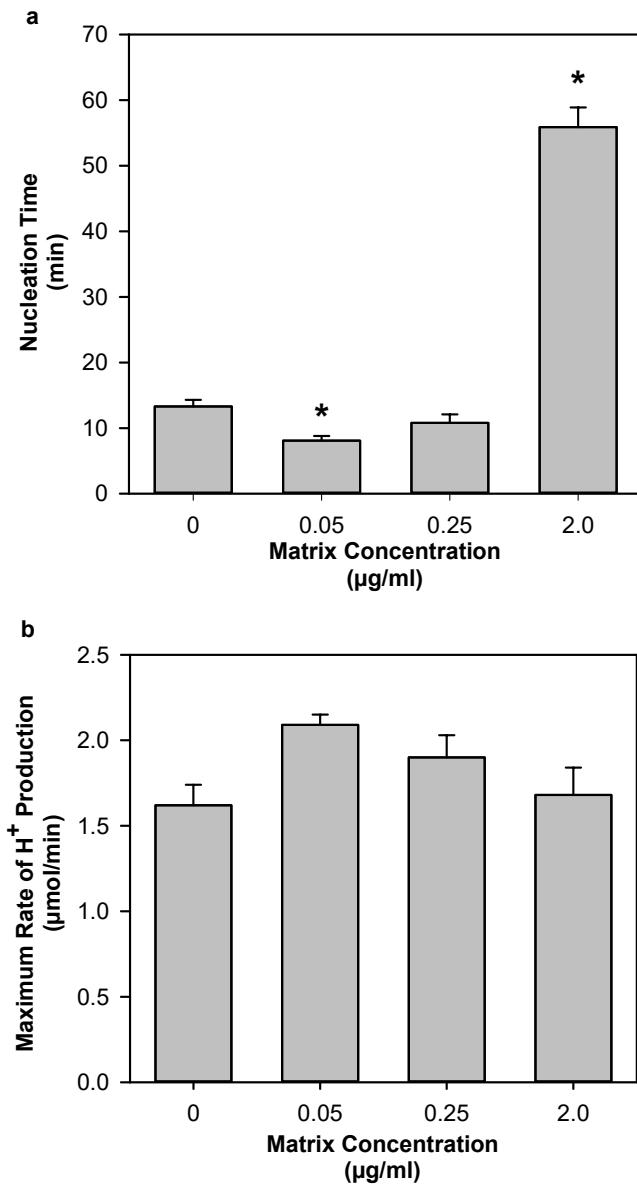

Supplementary Figure S3: Representative traces from the micro-modified *in vitro* calcification assay showing the comparison between pH (a) and H^+ concentration (b) and how nucleation time and calcification rate are calculated. Nucleation time (blue dashed line) is defined here as the time at which the pH or H^+ concentration has dropped or increased by 10% of the total change observed throughout the 20-hour assay. The calcification rate is calculated by taking the slope of a linear regression (red dashed line) fitted to the data between 20% and 60% of the total pH drop or H^+ concentration increase observed for the duration of the experiment. r^2 values for the linear regressions used to calculate calcification rate are also given, and show little difference between using pH or H^+ concentration.

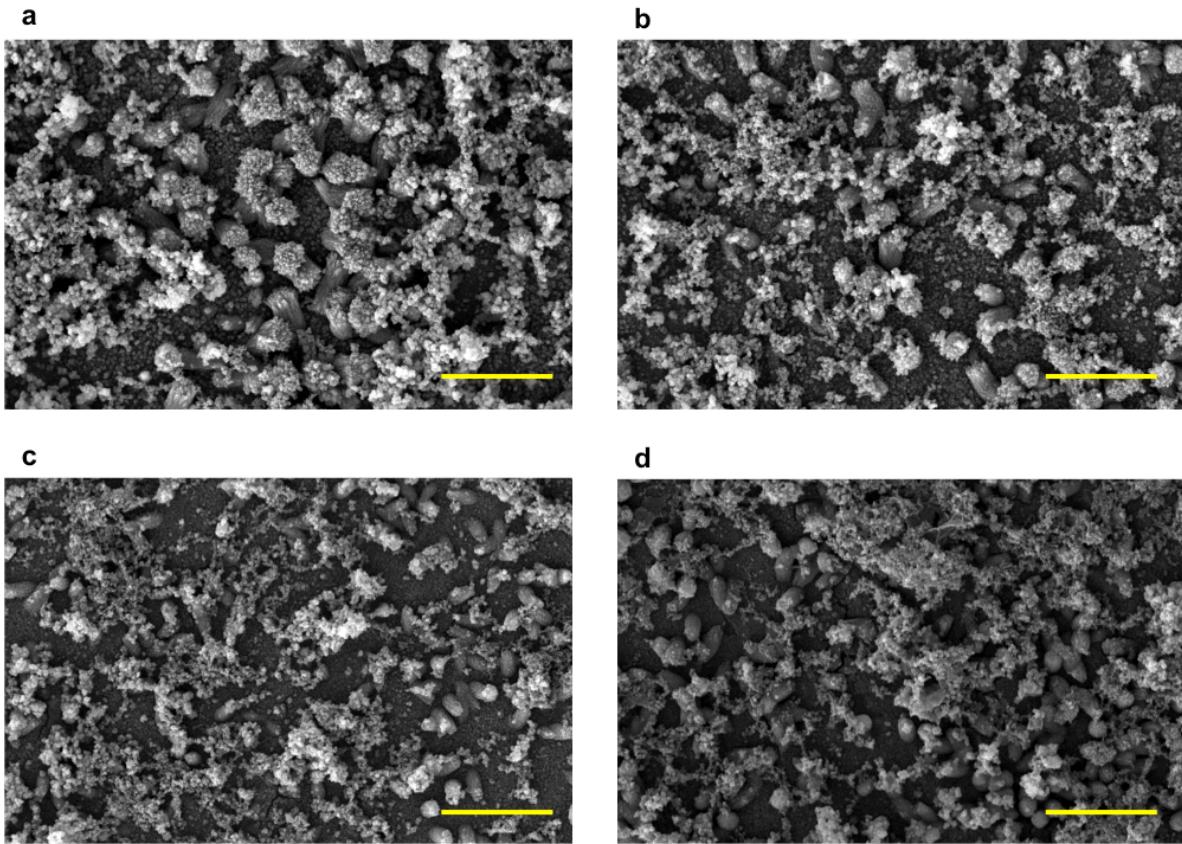

Supplementary Figure S4: The effect of BSA on *in vitro* CaCO_3 formation as compared to isolated precipitate organic matrix. Several concentrations of BSA were included in a calcification assay to determine if the effects observed in the presence of isolated organic matrix were due to non-specific protein interactions. Minor variations in both nucleation time (a) and calcification rate (b) were observed at the highest concentrations of BSA tested, but effects were minor compared to the precipitate matrix, suggesting the observed effects are not due to nonspecific protein interaction. Symbols (* BSA; † precipitate matrix) represent values that vary significantly ($p < 0.05$) from controls, as determined by two-tailed ANOVA and Holm-Sidak multiple comparisons.

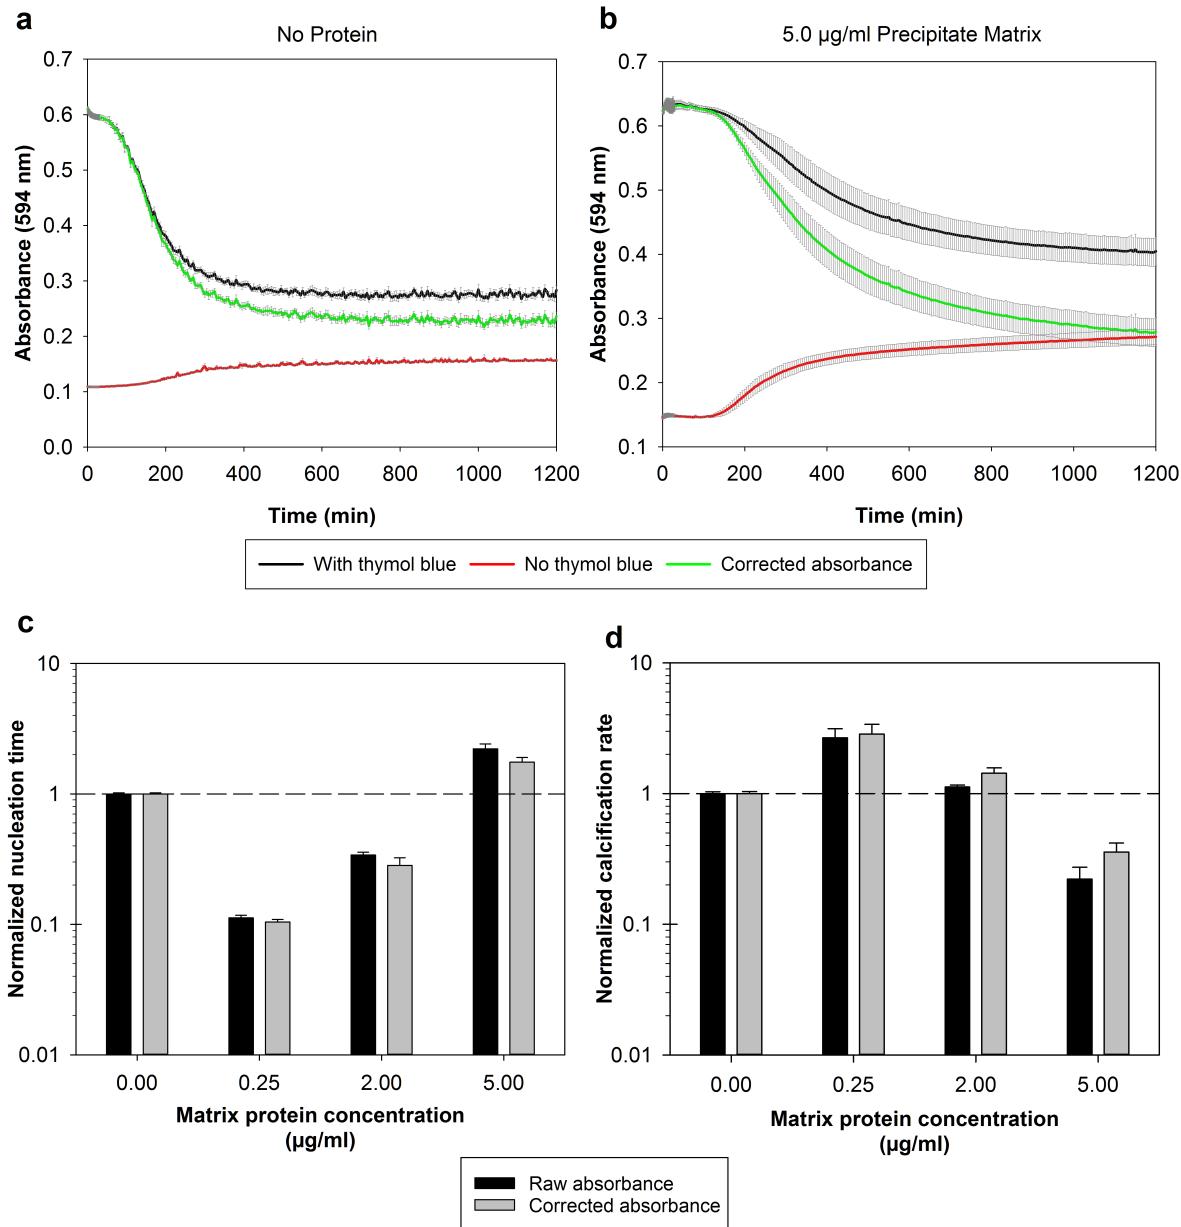

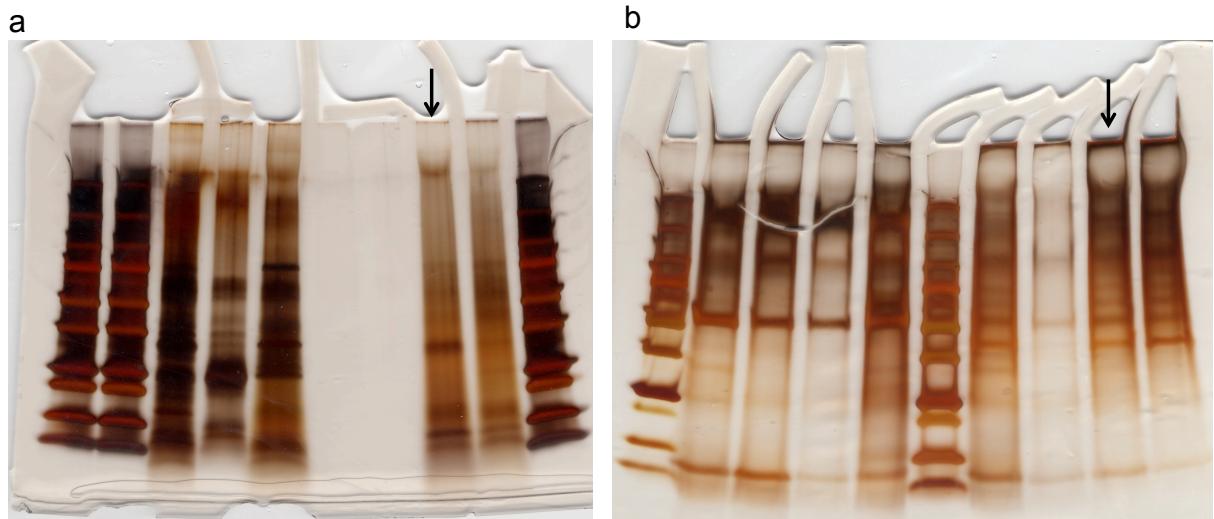

Supplementary Figure S6: Validation of micro-modified *in vitro* calcification assay using pH-stat. Purified intestinal CaCO_3 matrix were added to a pH-stat setup at several of the concentrations tested in the micro-modified calcification assay. **(a)** Nucleation time was defined as the point of max pH observed during the assay as the pH slowly drifts up prior to the start of calcification due to the outgassing of CO_2 . **(b)** Max calcification rate was determined to be the max rate of NaOH addition as averaged over at 20-second interval. * $p \leq 0.05$ compared to no protein control as determined by ANOVA and subsequent multiple comparisons by the Holm-Sidak method. $n=8$ for no protein controls and $n=5$ for all other treatments.

Supplementary Figure S7: Comparison of CaCO₃ crystal morphology formed *in vitro* in the presence of varying concentrations of purified intestinal precipitate matrix. **(a)** No protein, **(b)** 0.25 µg/ml matrix, **(c)** 2.0 µg/ml matrix, and **(d)** 5.0 µg/ml matrix. Scale bar = 20 µm.

Supplementary Figure S8: The effect of the formation of CaCO_3 on the absorbance measurements used to calculate pH during the micro-modified calcification assay. Identical pairs of samples were analyzed in the assay, but in one sample thymol blue was omitted from the salines. This allowed for the measurement of the absorbance at 594 nm (the wavelength used to monitor pH) over time due to the formation of the CaCO_3 itself. The absorbance from the wells lacking thymol blue was subtracted from their paired samples that contained thymol blue, and both the raw absorbance and the corrected absorbance values were used to calculate the pH throughout the assay. Raw absorbance values for the wells with and without the thymol blue, as well as calculated corrected absorbances are shown for controls wells containing no protein (**a**), as well as 5 $\mu\text{g}/\text{ml}$ of isolated precipitate matrix (**b**). Little change in nucleation time (**c**), or calcification rate (**d**) was observed using the two absorbances, suggesting that the formation of CaCO_3 has a minimal effect on the outcomes of the assay. Values are shown as mean \pm SEM. n=5-6.

Supplementary Figure S9: Uncropped images of the gels shown in Figure 1. **(a)** The gel in which the EDTA soluble sample was run, and **(b)** the gel containing the EDTA insoluble sample. Lanes shown in Figure 1 are marked with an arrow. Other lanes represent samples from unrelated experiments and should be ignored.

Supplementary Table S1: Description of the assembled *O. beta* transcriptomes. The original tissues from which RNA was extracted and eventually sequenced is listed along with the NCBI identifiers for the assembled transcriptomes and raw sequence reads. All results can be found under BioProject PRJNA313355.

Transcriptome abbreviation	NCBI BioSample identifier	NCBI SRA identifier	Included tissues
Muscle	SAMN04520031	SRR3193034	Heart, mixed skeletal muscle, sonic muscle, spleen
GI	SAMN04520030	SRR3193033	Liver, intestine, stomach, Brockmann body, gallbladder
Osmo	SAMN04520029	SRR3192986	Kidney, gill, urinary bladder, skin
Neural	SAMN04520032	SRR3193035	Brain, eye, gas gland, gonad

Supplementary Table S2: Protein identifications by mass spectrometry in matrix extracted from precipitates purified using the gentle purification procedure. Biological replicates are listed separately and labeled numerically. Probable protein identifications were determined by BLAST of the NCBI non-redundant database. Proteins in gray are known contaminants from the cRAP database. Proteins in bold and italics contain known calcium binding domains. Accession numbers refer to *de novo* assembled transcripts and have been truncated for clarity.

Supplementary Table S3: Proteins identified by mass spectrometry in the intestinal fluid as well as the isolated intestinal precipitate matrix purified using the stringent method. Numbers in the table headers denote biological replicates. Proteins in gray are contaminants identified from the cRAP database. Proteins in bold and italics were observed in the matrix samples and contain known calcium binding domains. Accession numbers refer to *de novo* assembled transcripts and have been truncated for clarity.

Supplementary Table S4: Composition of the salines used in the micro-modified *in vitro* calcification assay, pH-stat, and electron microscopy (EM) experiments. For the pH-stat and EM experiments the thymol blue was omitted. The calcium buffer, bicarbonate buffer, and TBS (containing matrix proteins if appropriate) were mixed to result in a final ratio of 9:9:2 in the assays.

Salt	Concentration in calcium buffer	Concentration in bicarbonate buffer	Concentration in TBS	Final assay concentration	Standard curve buffer
NaCl	60 mM	60 mM	150 mM	69 mM	69 mM
KCl	5.56 mM	5.56 mM	--	5 mM	5 mM
MgSO ₄	86.11 mM	86.11 mM	--	77.5 mM	77.5 mM
MgCl ₂	25 mM	25 mM	--	22.5 mM	22.5 mM
NaHCO ₃	--	55.56 mM	--	25 mM	25 mM
CaCl ₂	44.44 mM	--	--	20 mM	20 mM
Tris Base	--	--	10 mM	1 mM	100 mM
Thymol Blue	0.0044%	0.0044%	--	0.004%	0.004%
pH	8.6	8.6	7.5	--	--
