Supplementary figures S1-S9

Supplementary tables S1-S8

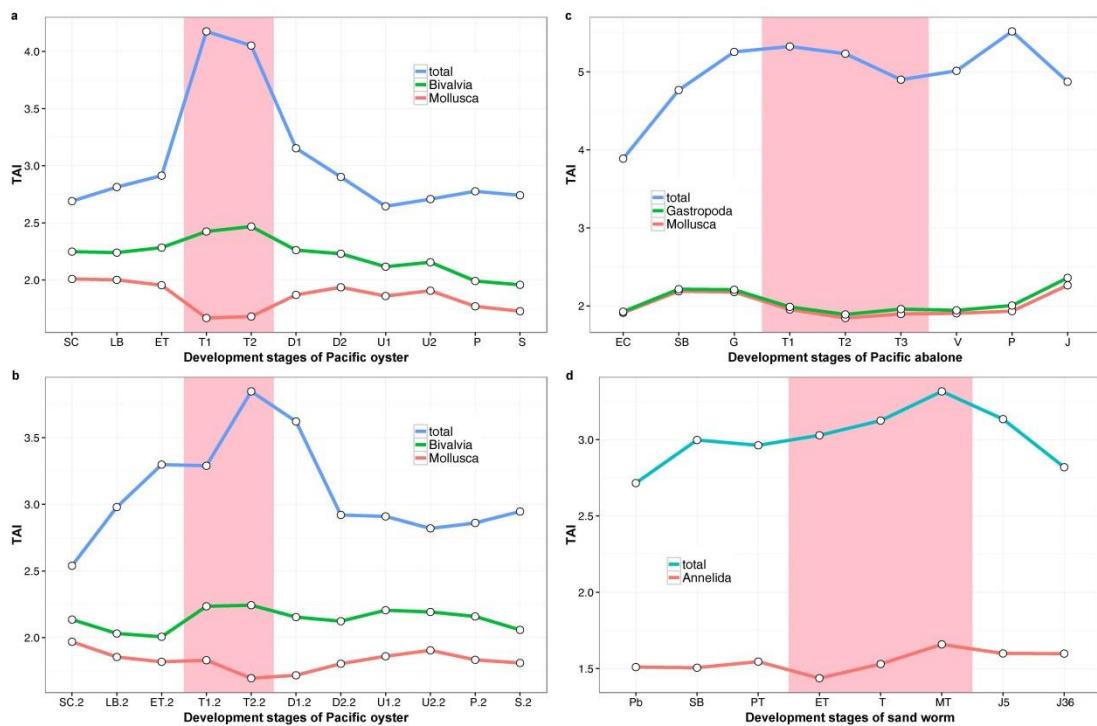

Figure S1 | Transcriptome age indices across the ontogeny of the Pacific oyster, *Crassostrea gigas* (a and b indicate the two experimental replicates), the Pacific abalone, *Haliotis discus hannai* (c), and the sand worm *Perinereis aibuhitensis* (d). The blue lines indicate the total cumulative value of the TAI. The green lines in panels a and b show TAI calculated for phylostrata older than Bivalvia (ps1-ps10). The green lines in panel c represent TAI calculated for phylostrata older than Gastropoda (ps1-ps10). The red lines in panels a, b, and c show TAI for phylostrata older than Mollusca (ps1-ps9), while the red line in panel d represents TAI for phylostrata older than Annelida (ps1-ps9). The developmental stages and their timelines are defined in Table S1-S4. The area with pink background designates the trophophore stage of each species.

The expression profile of oyster specific genes in development

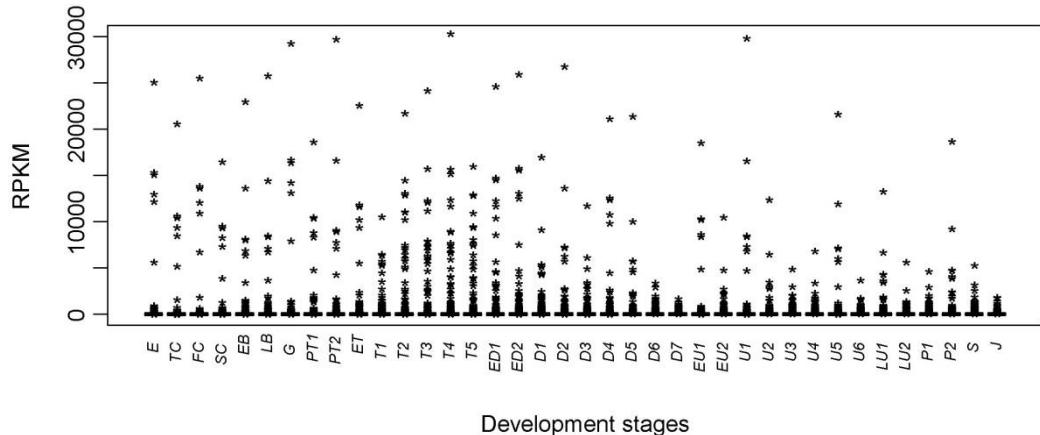

Figure S2 | Distribution of RPKM value of all the annotated genes in the genome across different development stages. Some genes showed high expression level at trophophore stage, mainly including 51 genes from ps11 (oyster-specific) and 5 genes from ps10 (Bivalvia-specific). Details of these 56 genes were shown in Table S1.

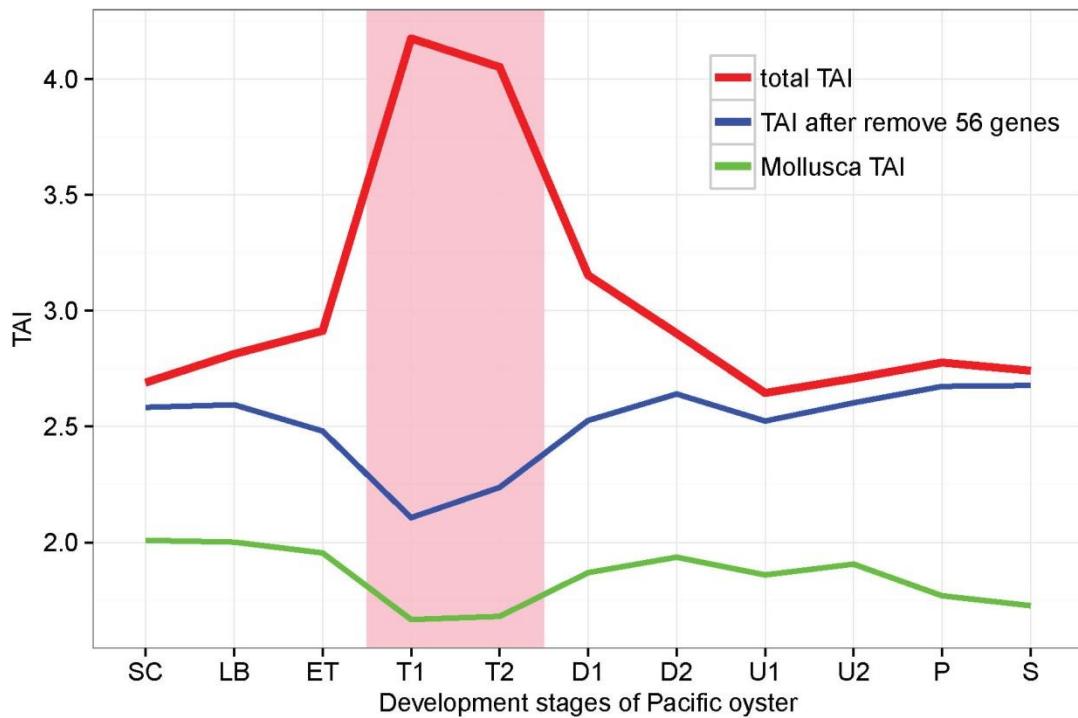

Figure S3 | Dissection of the TAI composition by isolating the 56 genes (shown in Figure S3 and Table S1) mainly contributing to the high TAI value at trophophore stage.

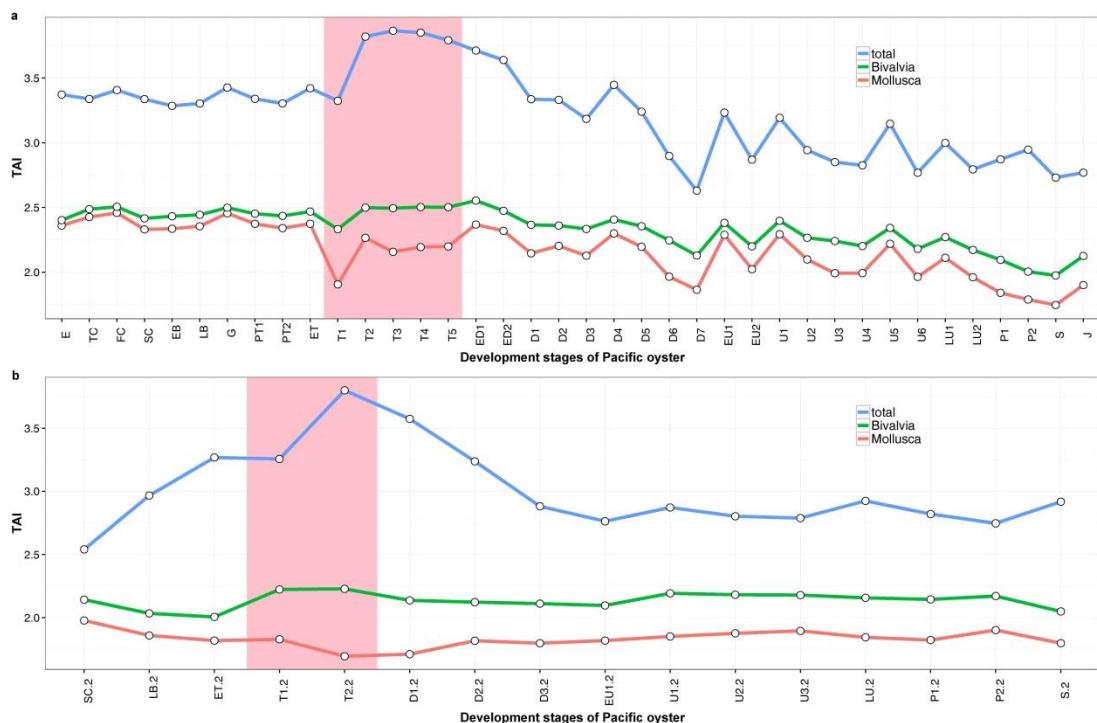

Figure S4 | Transcriptome age indices across the ontogeny of the Pacific oyster, *Crassostrea gigas*. TAI values for all the sequenced development stages were calculated using all the predicted genes of each genome genome. It can be seen that the selected typical development stages shown in Figure S1a & S1b can well reflect the pattern in this figure.

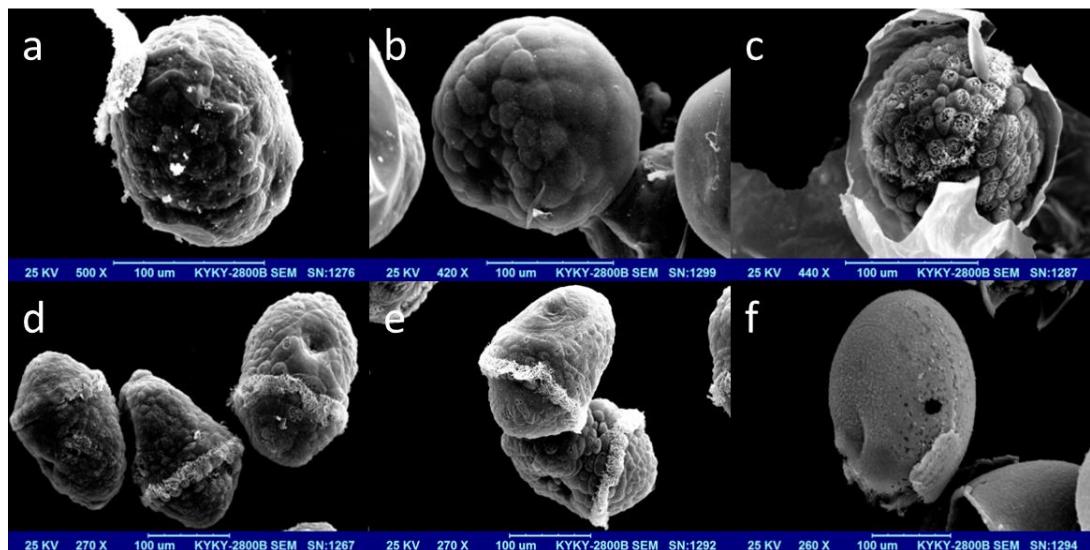

Figure S5 | The embryonic and larval development of Pacific abalone *Haliotis discus hannai*.

a. Stereoblastula stage at about 200 min post fertilization. **b.** Gastrula at 6 h post fertilization. **c.** Trochophore at 10.5 h post fertilization. The larvae was still in the egg envelope. **d.** Trochophore at 13.5 h post fertilization. Free swimming larvae hatched, and the shell field formed. **e.** Early veliger larvae at 15 h post fertilization. The shell field expanded at the dorsal side of the larvae. **f.** Veliger larvae at 25 h post fertilization. The calcified adult-like shell formed.

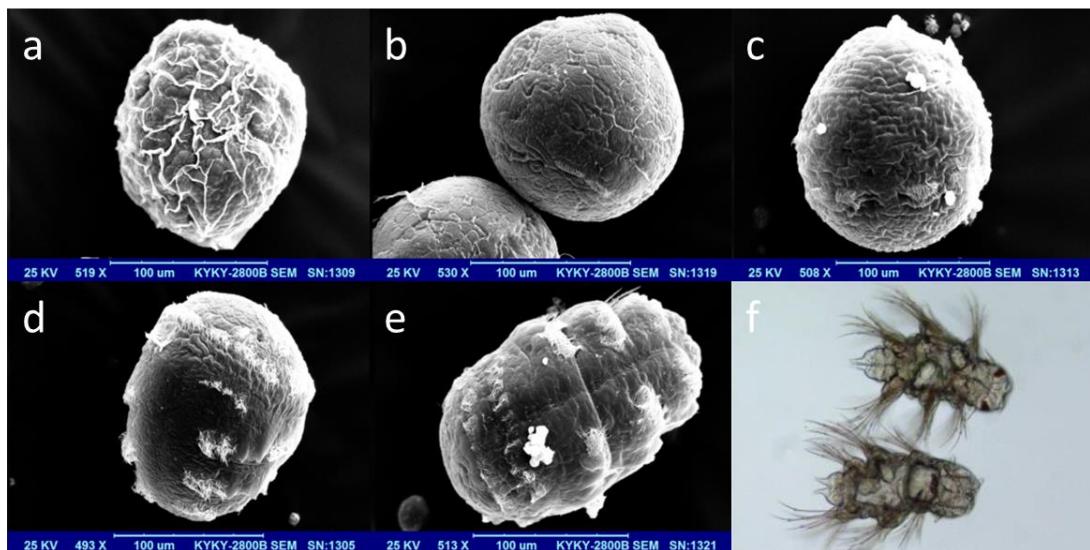

Figure S6 | The embryonic and larval development of sand worm *Perinereis aibuhitensis*.

a. Stereoblastula stage at 8 h post fertilization. The white lines at the surface of the embryo were wrinkles formed by the jelly around the embryo. **b.** Protrochophore at 14 h post fertilization. **c.** Trochophore at 26 h post fertilization. The larvae was still in the jelly. The prototroch formed at this stage. **d.** Metatrochophore at 30.5 h post fertilization. Three segments are visible, and the chaetae formed in the trunk. **e.** Juvenile in the jelly with three setigers (or metatrochophore), 36 h post fertilization. **f.** Juvenile with three setigers (or nectochaete) at 2.5 d post fertilization. This photo was taken with the light microscope.

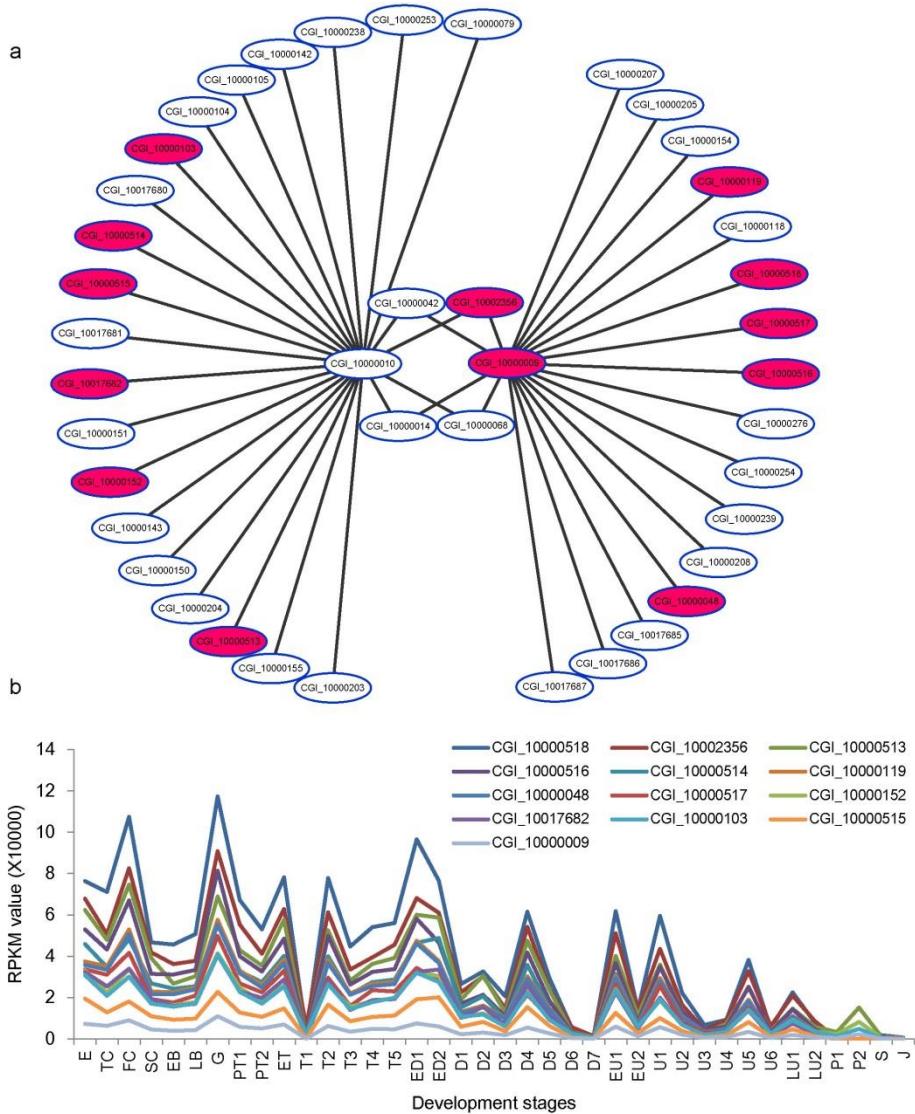

Figure S7 | Genes filtered out through the expression pattern.

Thirteen additional genes were discarded (the red color filled ellipses in panel a, and the genes listed in panel b) during the TAI analysis. These genes showed very similar expression pattern (Pearson correlation coefficients were larger than 0.99, panel a & b) and fluctuating expression curve along the ontogeny (panel b). They had short nucleotide sequences (186-465 bp) and extremely high expression levels in most samples (RPKM was as high as 120,000). These genes were thus considered to be some kind of special genomic elements, such as retrotransposon.

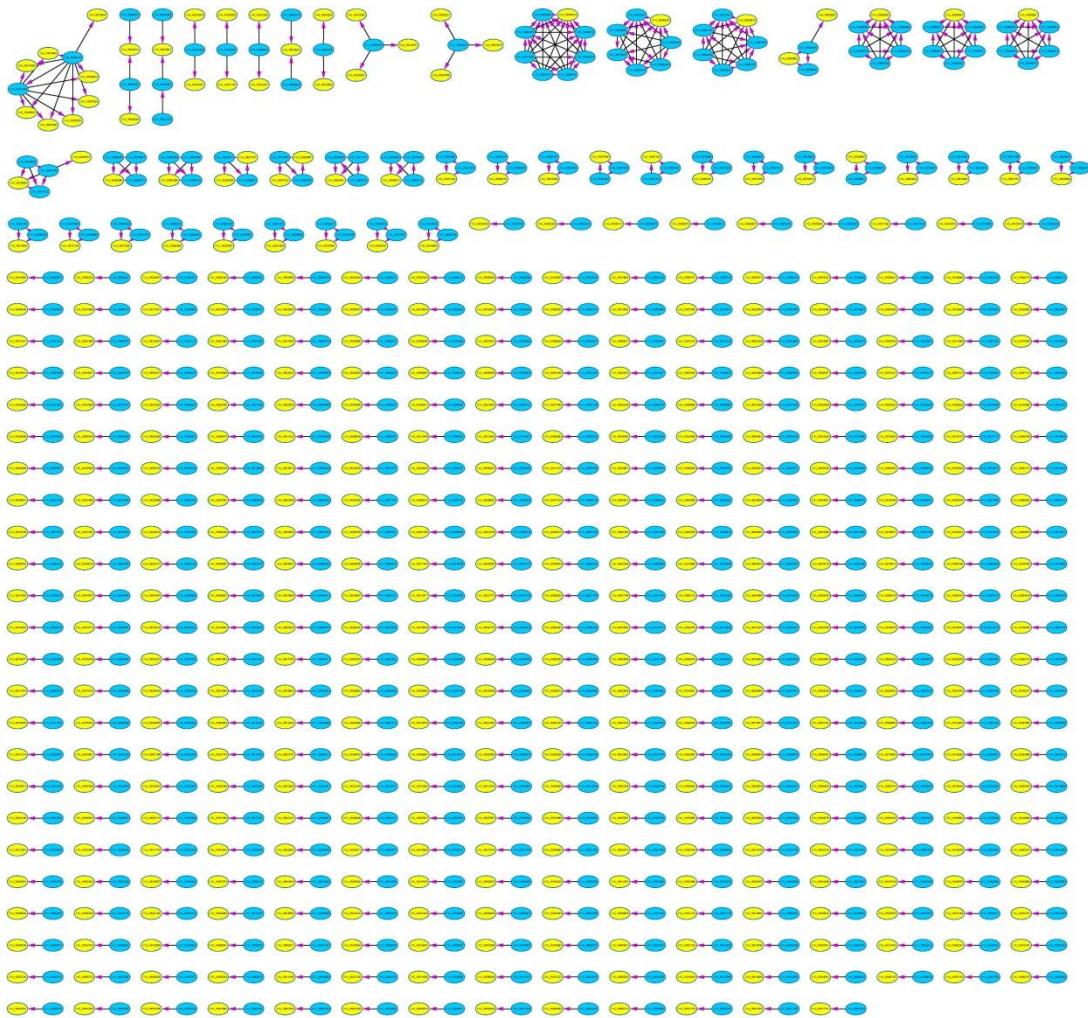

Figure S8 | Genes filtered out through sequence redundant analysis.

The ellipse filled with yellow color shows the genes which were retained, while the blue filled color shows the genes which were discarded. The target (the ellipse arrow is pointing) was defined as the genes with equal or larger length than the source (the ellipse at the other side of the arrowed line). In this case, all the source genes were discarded, and only the gene which was target for all the related genes (there are only arrow point around the gene) was retained. The following criteria were used to identify redundant genes: 1. When the query and target genes had different length, the shorter one should aligned onto the longer one completely. 2. The protein sequences should be at least 97% identities in the alignment region, while the DNA sequences should be at least 95%. 3. There should be not any gap in the aligned protein region.

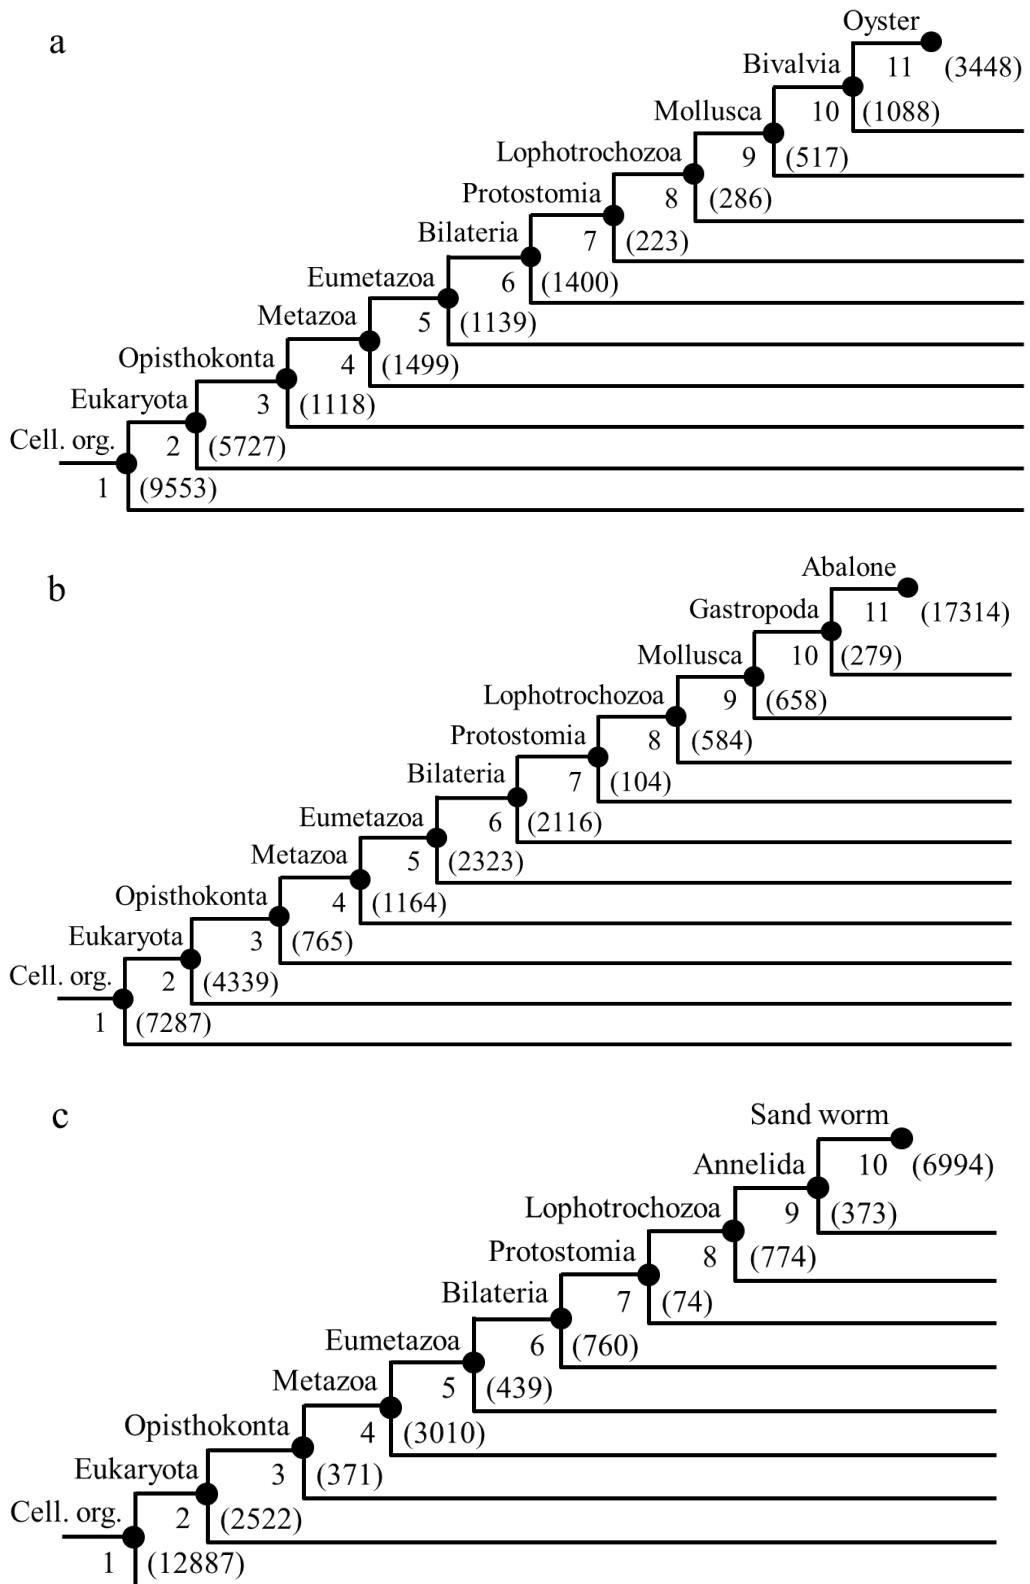

Figure S9 | Phylostratigraphic map of oyster (a), abalone (b) and sand worm (c).
The numbers at the lower left of each spot denote the number phylostrata, while the numbers in parenthesis at the lower right denote the number of genes per phylostratum. Cell. org., cellular organisms.

Table S1 | Details of the 56 genes highly expressed in trochophore stages, and mainly contributing to the high value of the total TAI. “NA” in the IPR, GO, KEGG, TrEMBL columns indicate the corresponding annotation is not available. Value in each development stage is the TAI value of each gene in the corresponding development stage (calculated by $p_i f_i$, see reference 10 in the main text for more details).
