

Supplemental Material

Figure S1. Histograms of raw scores of 308 JASPAR TFBS matrices.

Histograms of raw scores of 308 JASPAR TFBS matrices were derived from upstream 1 kb promoter regions of all available RefSeq genes for hg18 (build 36) (20369 human-mouse-rat alignments, 20.4 Mb of human, 13.7 Mb of mouse and 13.4 Mb of rat sequences). The occurrences of raw scores within each 0.001 bin was recorded and plotted (red). The normal distribution was fitted to the observed values and superimposed on the histogram plots (black).

Table S2. Properties of raw score histograms for JASPAR TFBS matrices.

Properties of raw score histograms were determined using SAS Proc Univariate, including mean, standard deviation, Kolmogorov-Smirnov distance (KS distance), skewness and kurtosis. Based on whether MEAN + STDEV < 0.5, KS distance > 0.1 and Skewness > 0.2, All 308 JASPAR TFBS matrices were assigned into one of eight types of histograms. For PF collections, the TF names were not available and their distributions in Types 6 and 8 histograms were associated with their degenerate bases and short length.

Table S3. Thresholds of JASPAR TFBS matrices at various cutoffs.

For each species, a series of cutoffs (from the top 0.01% to 10% of all predictions) were calculated using all predicted sites from all available RefSeq genes. Since TFLOC only reports a conserved binding site meeting the threshold in all 3 species, the lowest raw score among 3 species was chosen for the final threshold at each cutoff.

Table S4. Custom tracks in the UCSC genome browser.

Known and predicted sites were displayed as custom annotation tracks using the “pack” mode in the UCSC genome browser. The datasets in the BED format were organized as known, newly predicted tracks and the prediction tracks were organized according to the sources and the JASPAR collection.

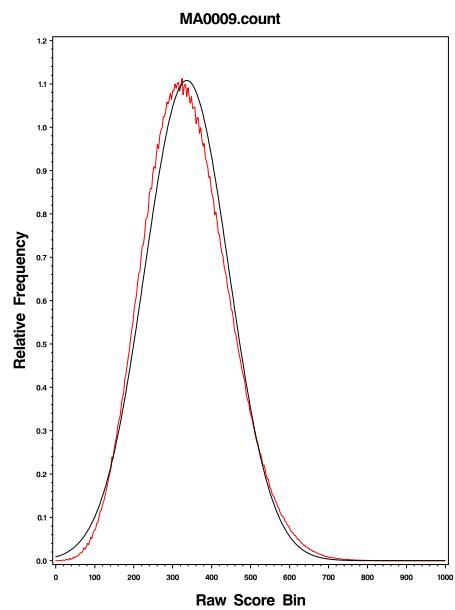

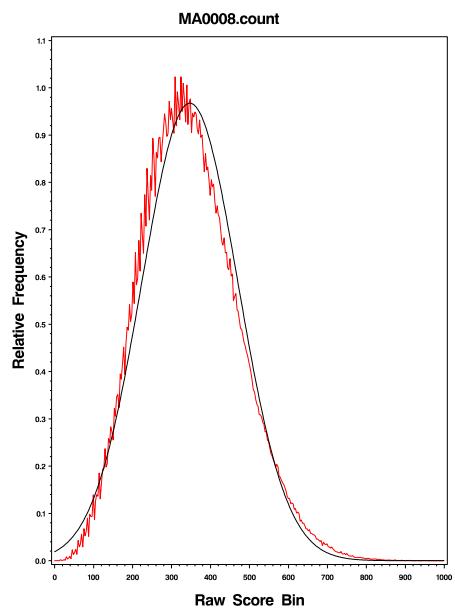

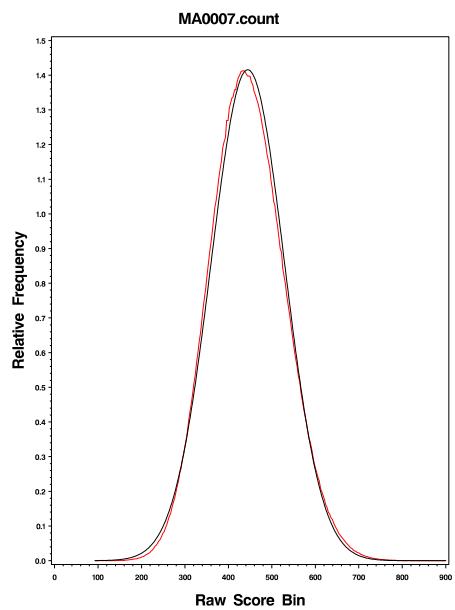

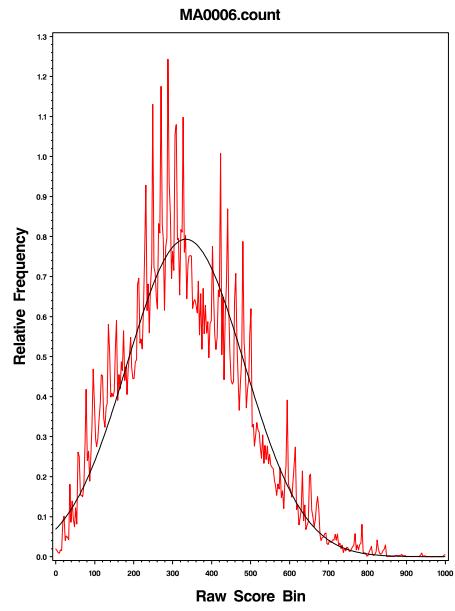

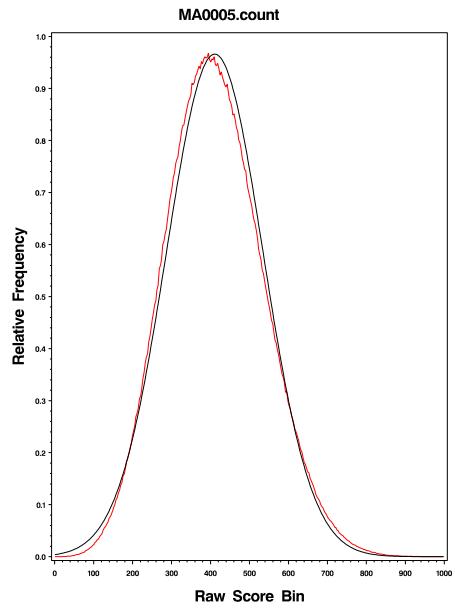

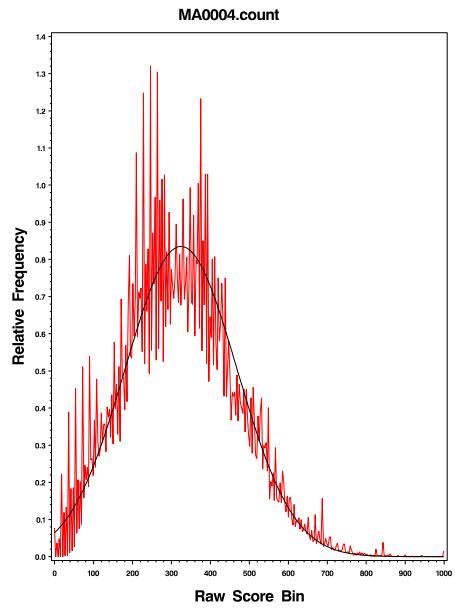

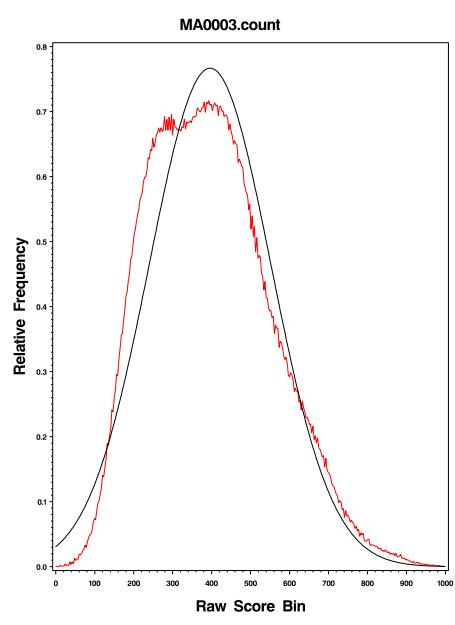

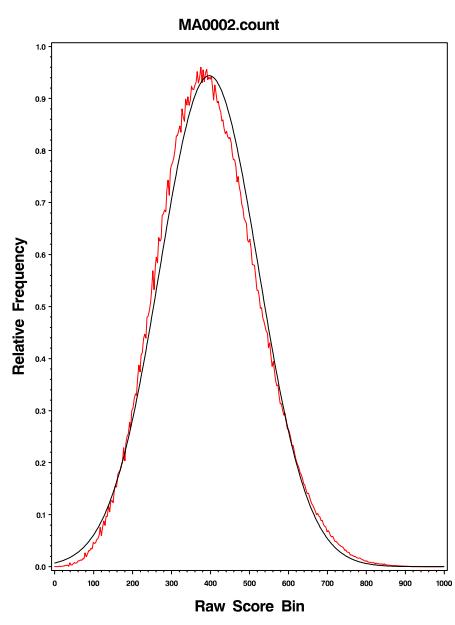

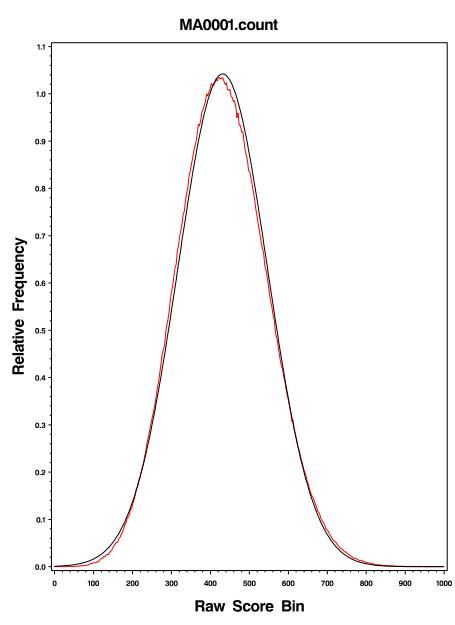

Table S5. Overlap relations between known and predicted sites.

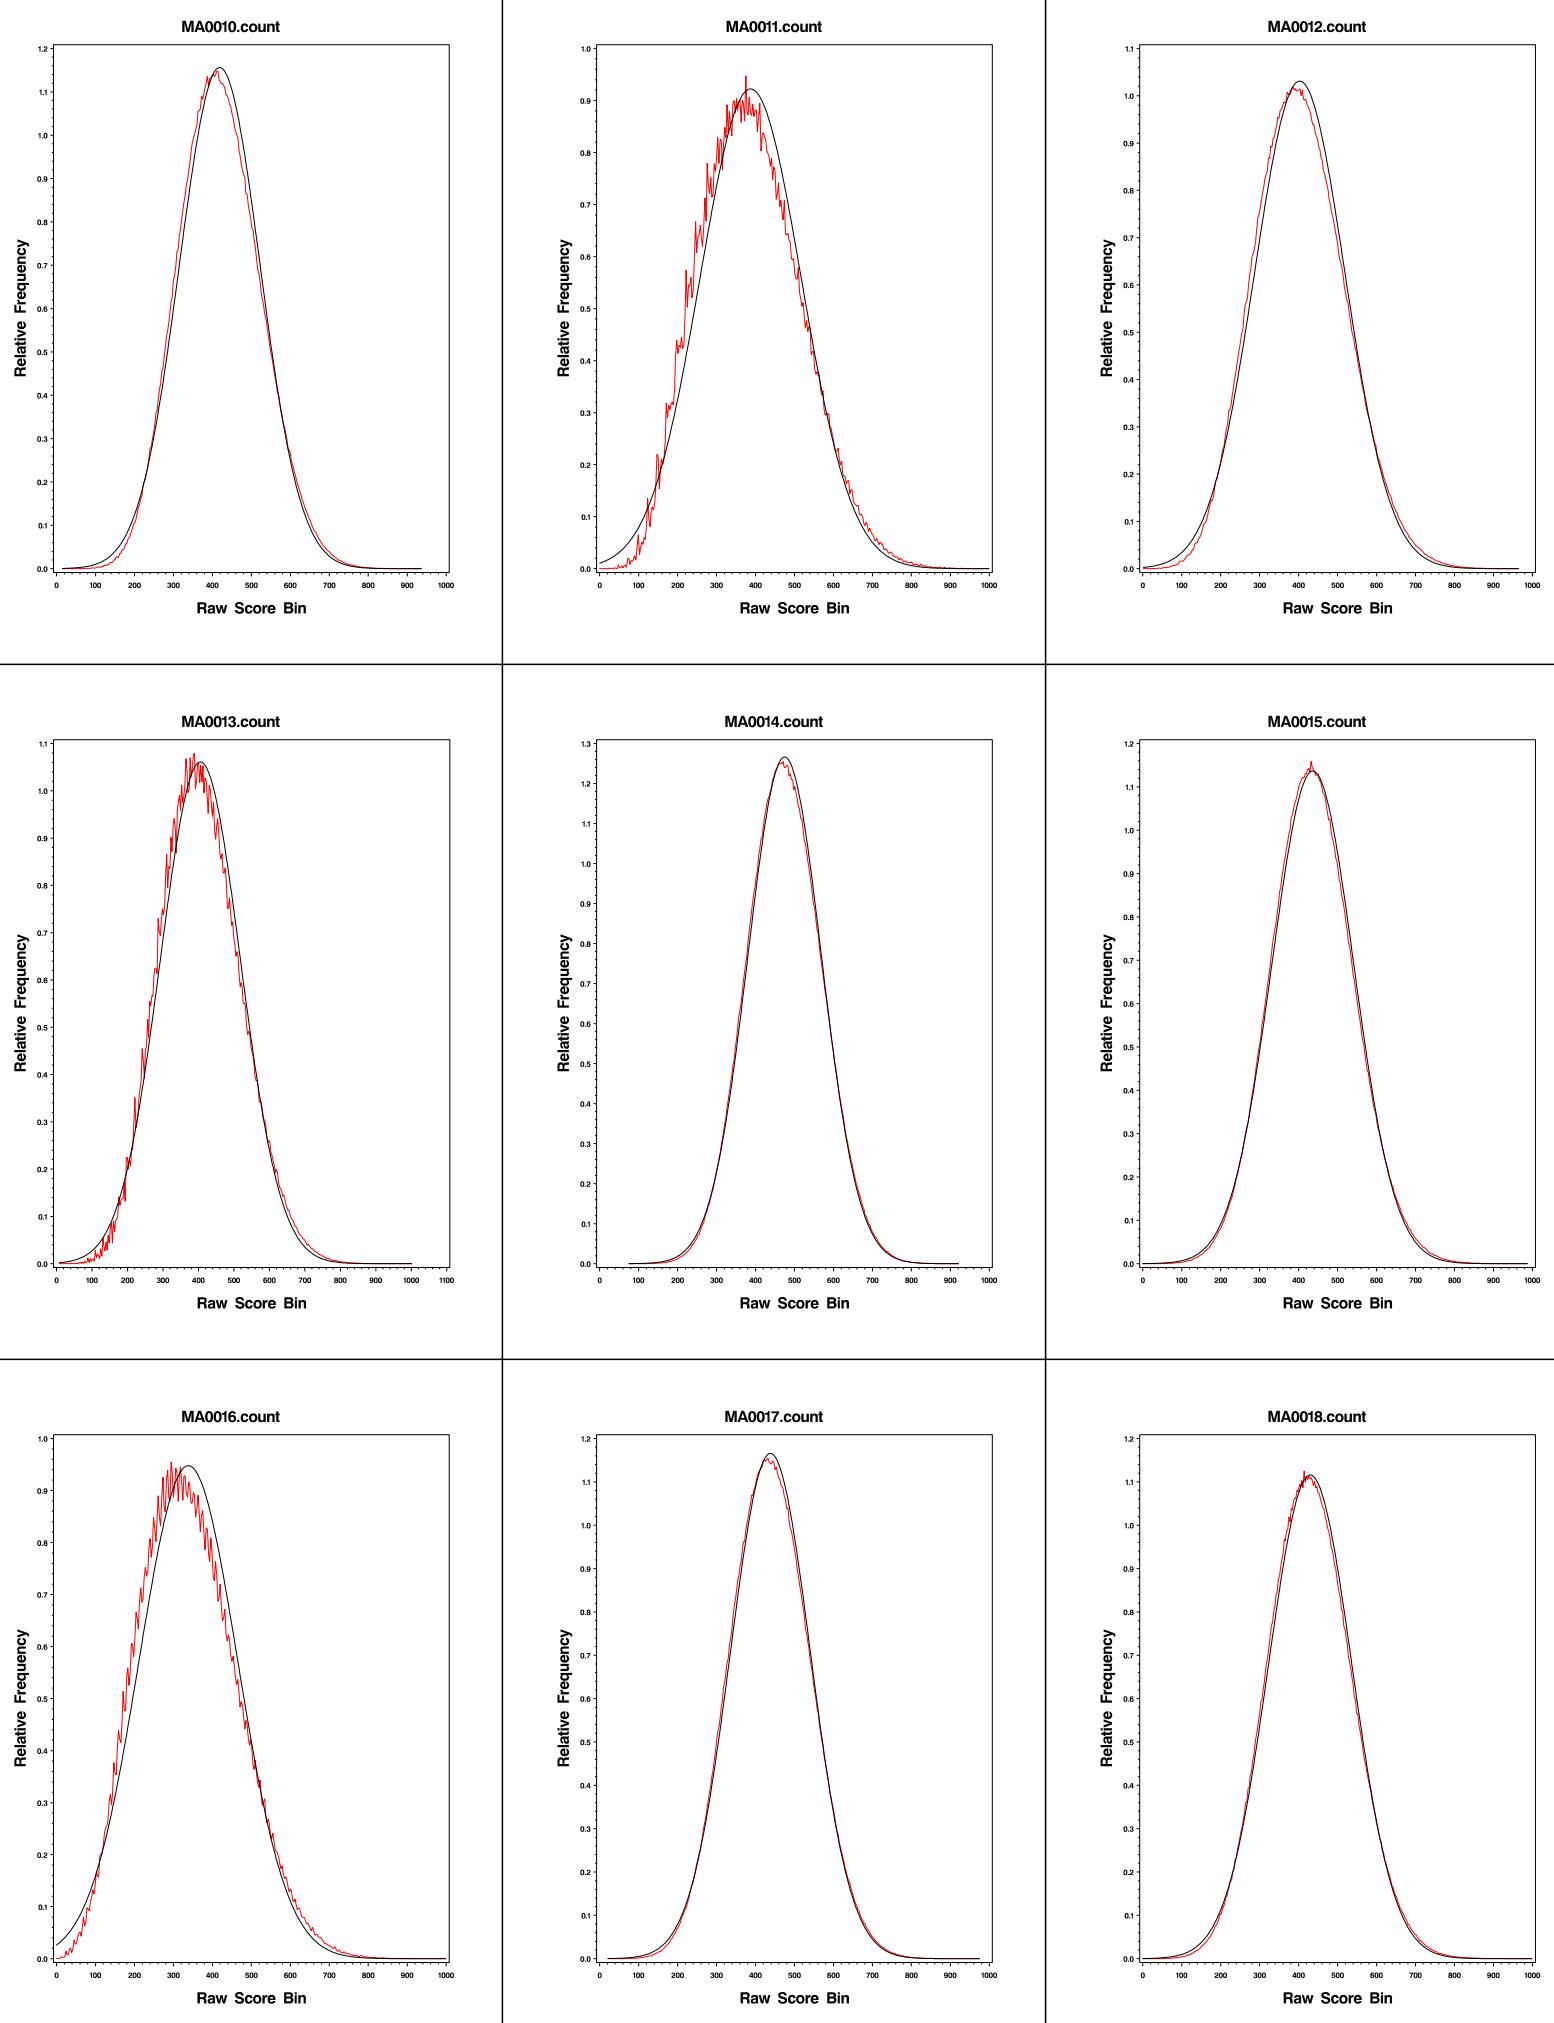

Based on the positions within alignments, the overlap relation was determined between the known and predicted sites. A. When considering mutual overlaps with coverage greater than 50%, only 4 sites were missed as described in Results (GRE, SREBP, NF1/CTF1, and CRE-2). B. When considering any overlap, CRE-2 was the only one missed, which turned out to be rodent-specific. All other known TFBS overlapped the predictions.

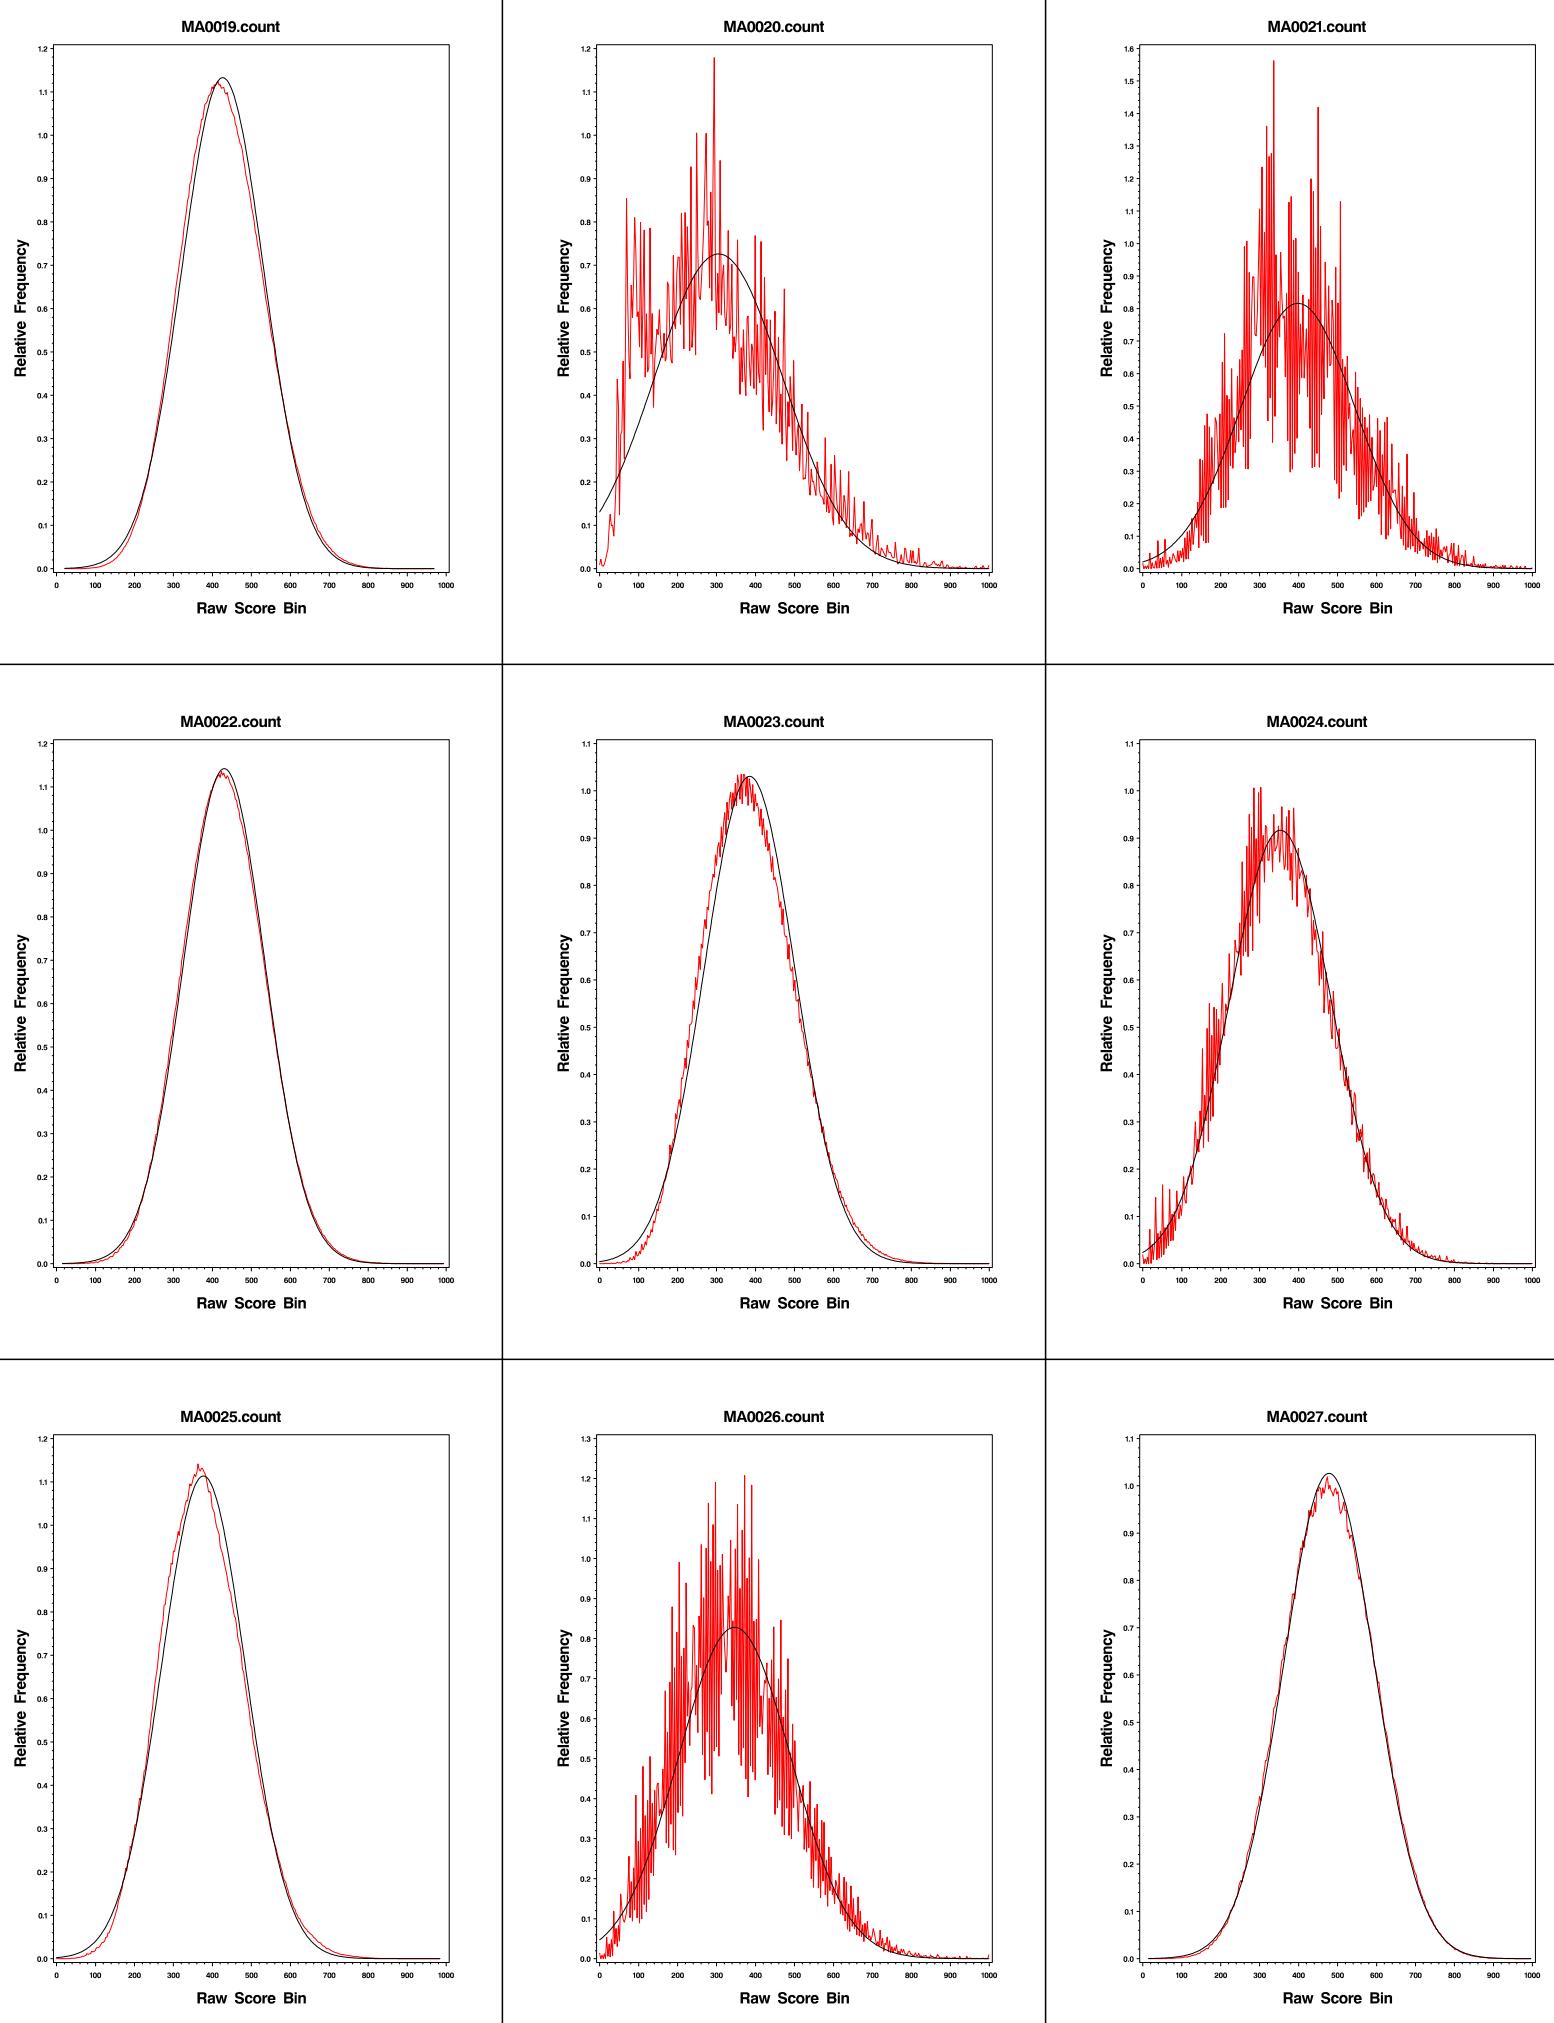

Table S6. Overlap relations between newly discovered and predicted sites.

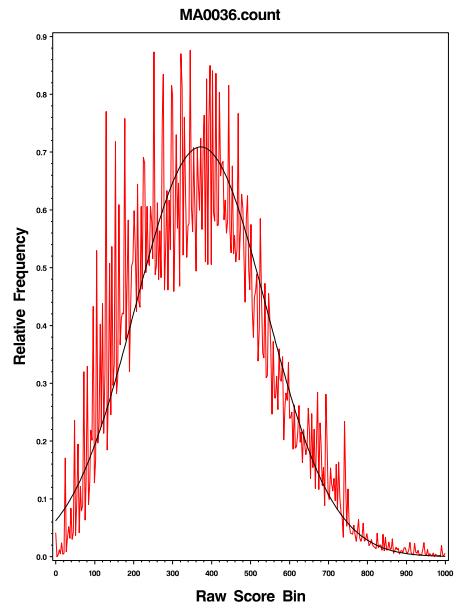

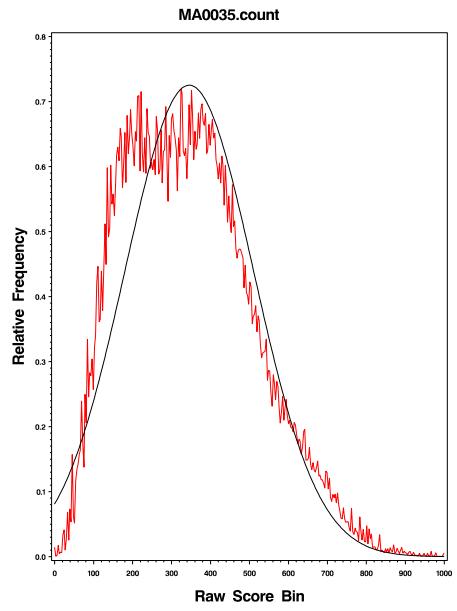

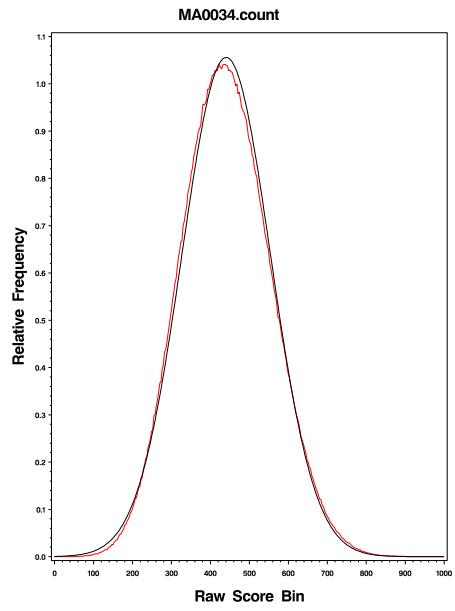

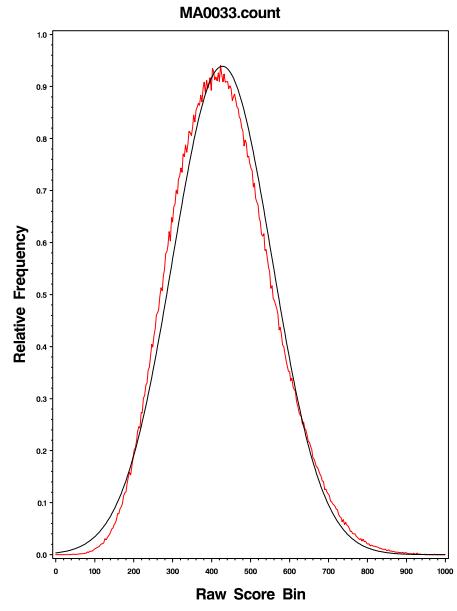

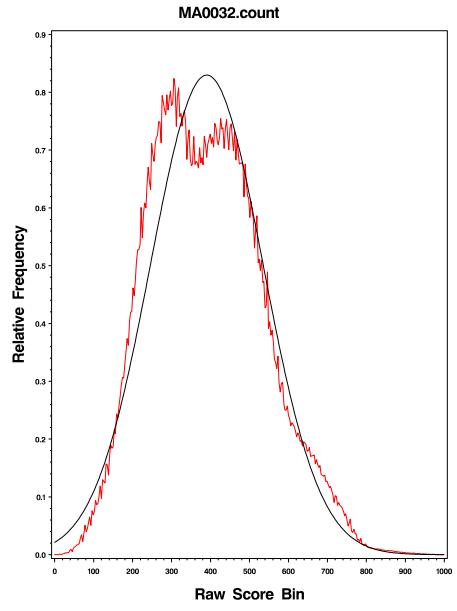

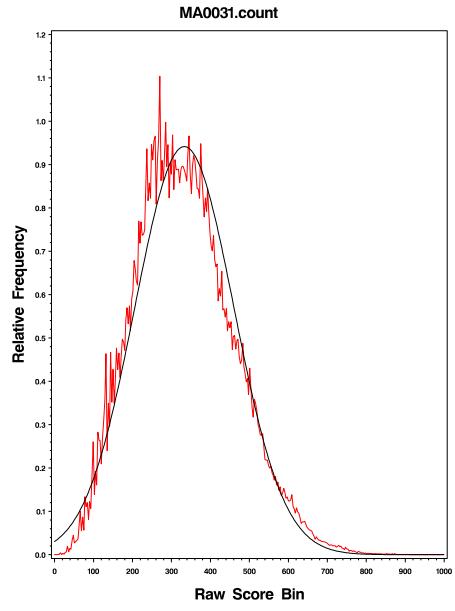

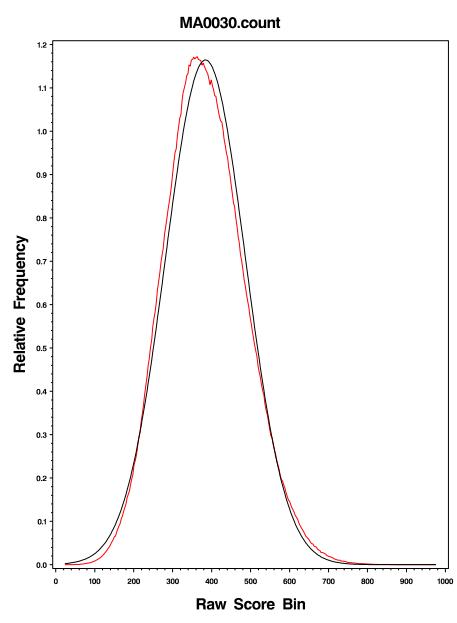

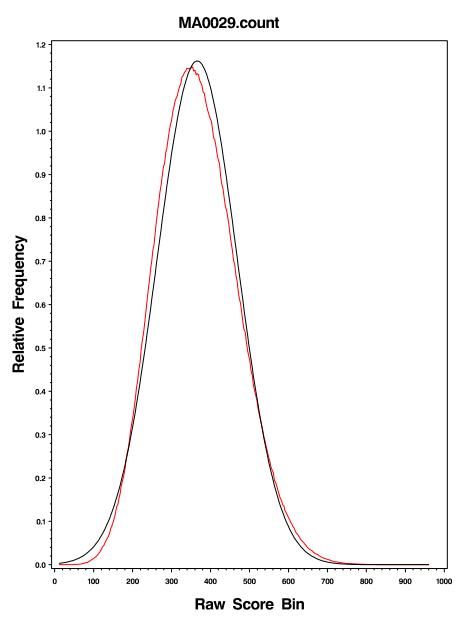

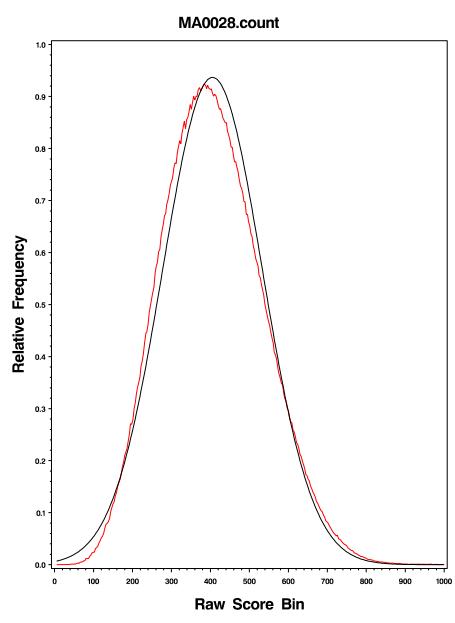

There were 7 potential novel sites with strong sequence conservation across species. They were listed in Supplemental Table S4 and displayed as a separated track (blue) in Fig. 2. For the 5 newly discovered proximal TFBS, their overlap relations with predictions were listed:
A. Mutual overlaps with coverage greater than 50%. B. All overlaps.

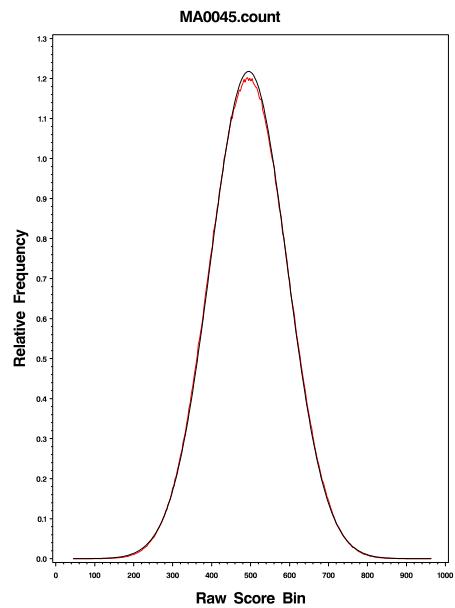

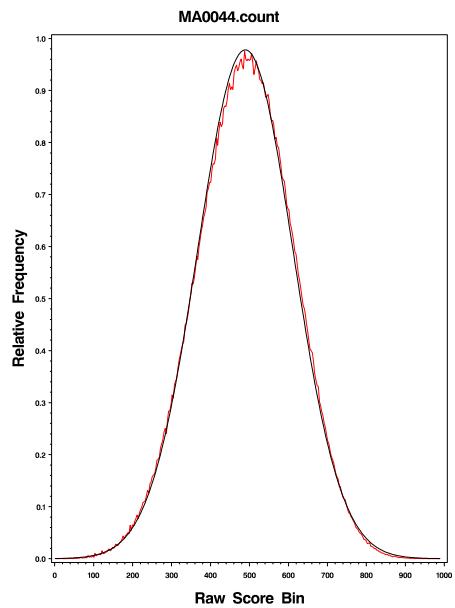

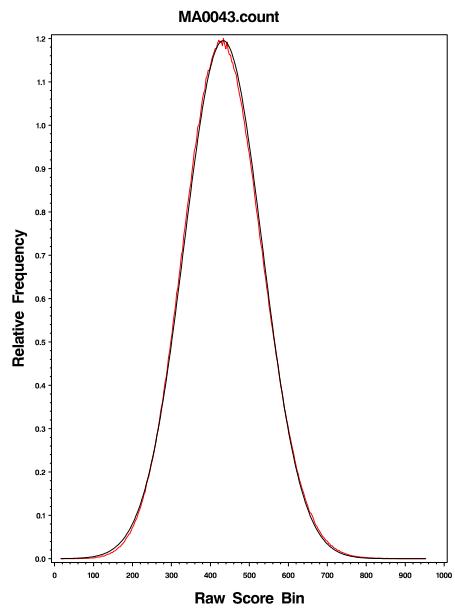

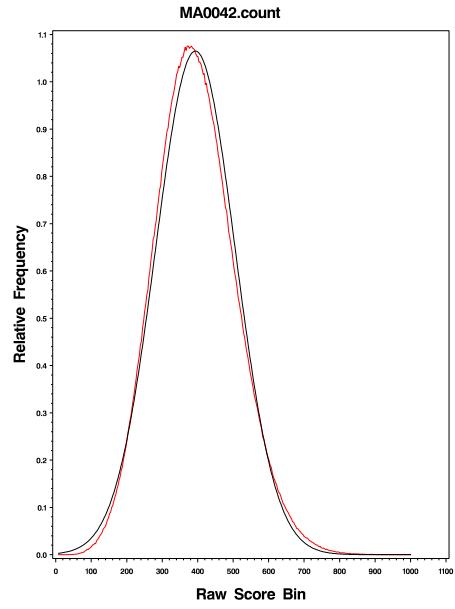

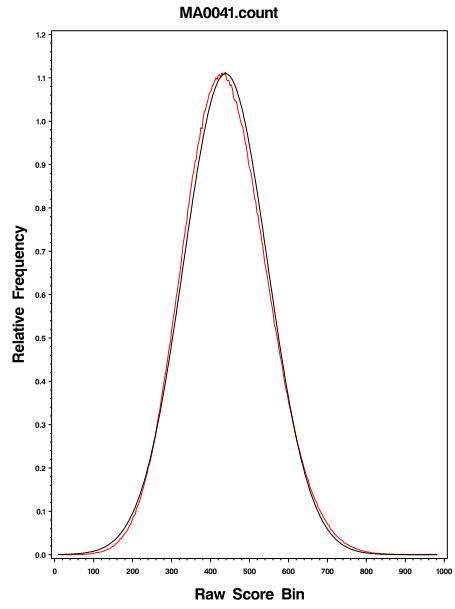

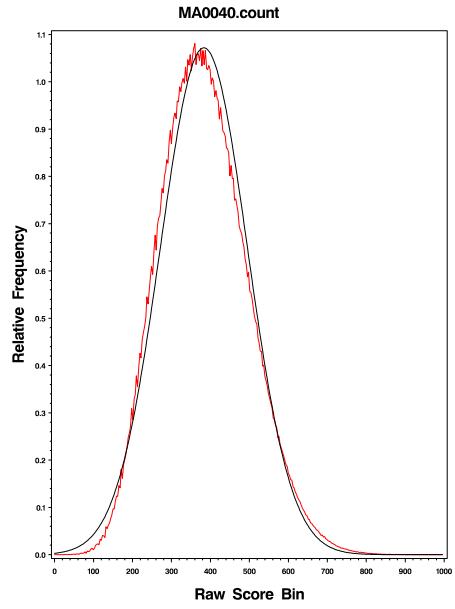

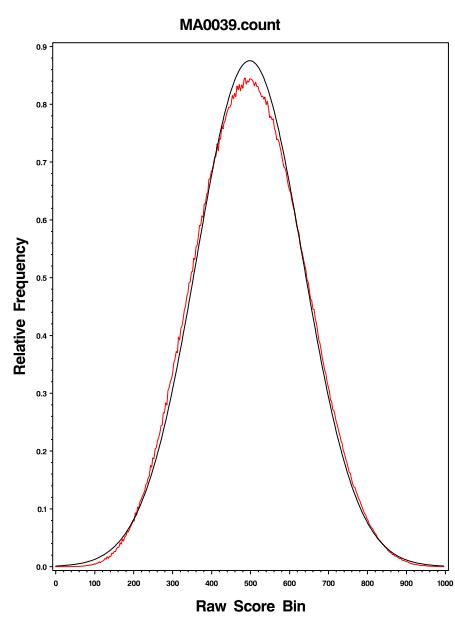

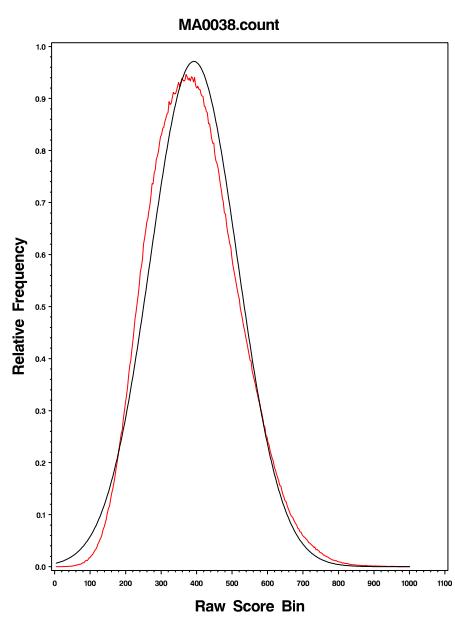

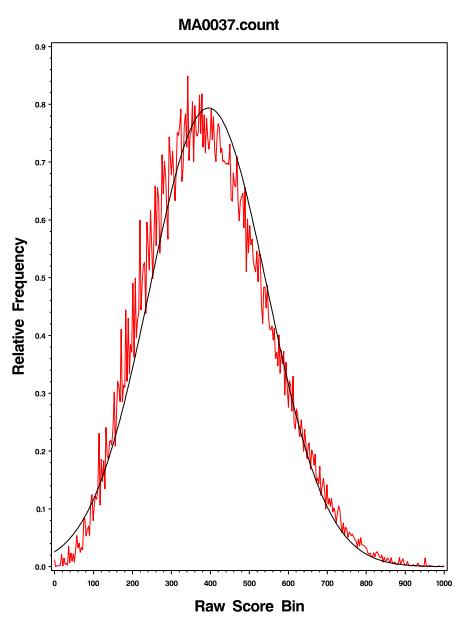

Figure S1. Histograms of raw scores of 308 JASPAR TFBS matrices.

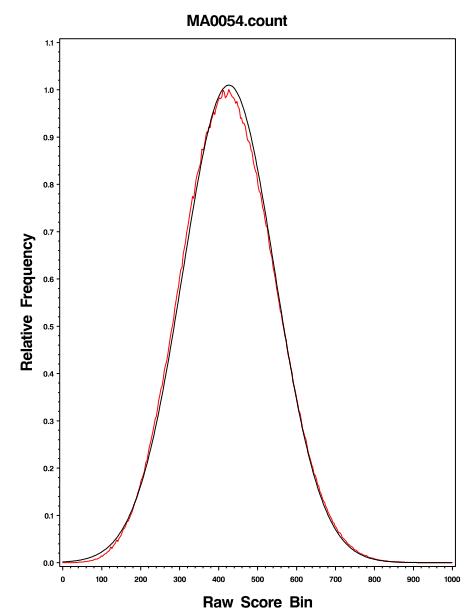

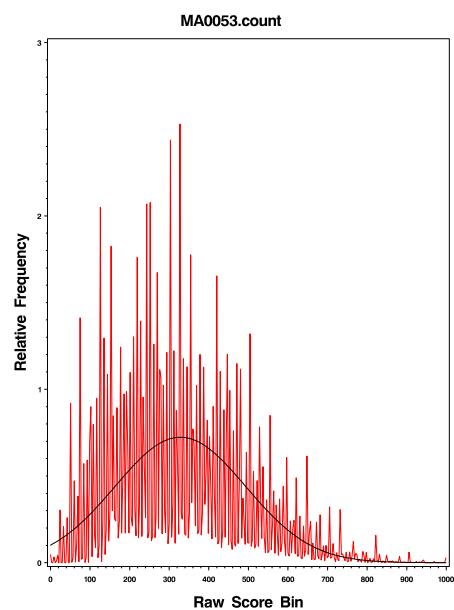

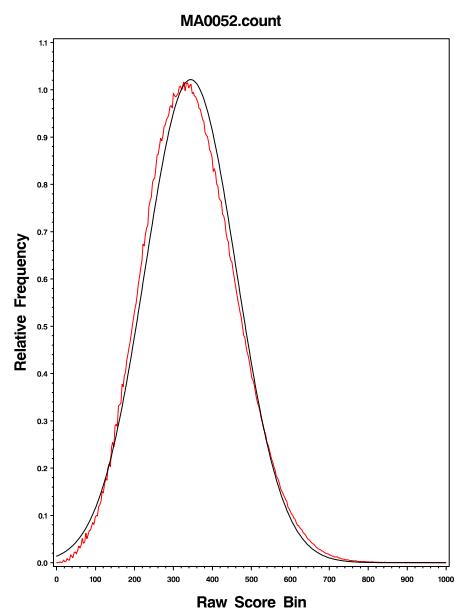

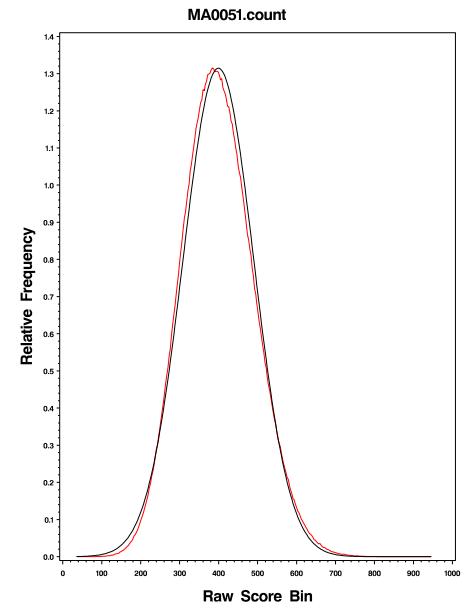

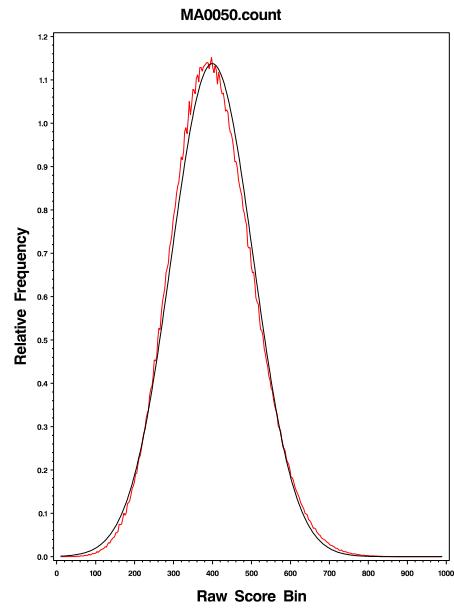

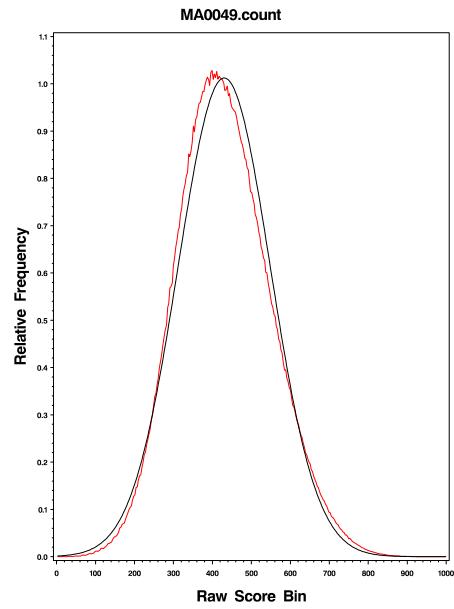

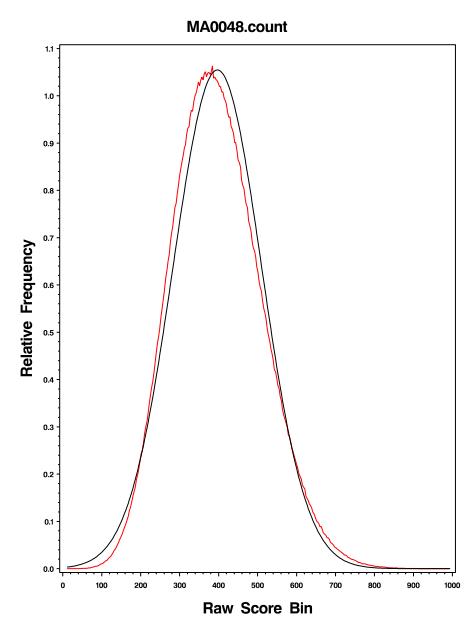

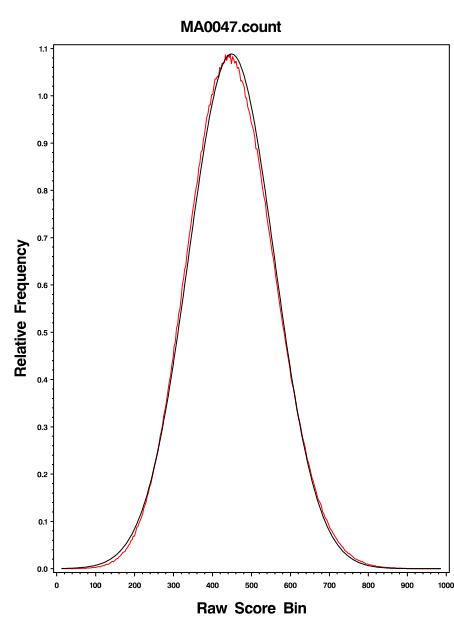

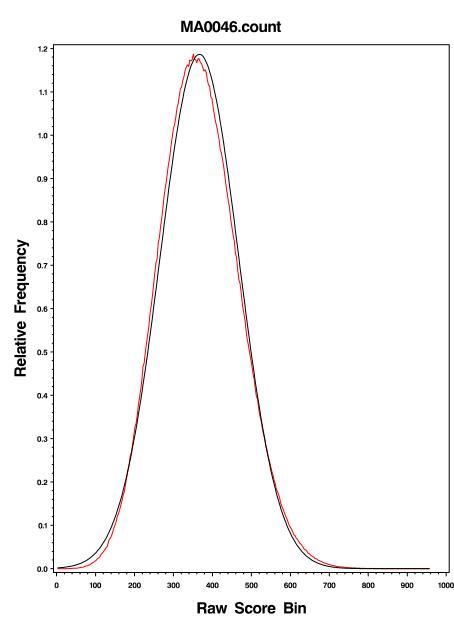

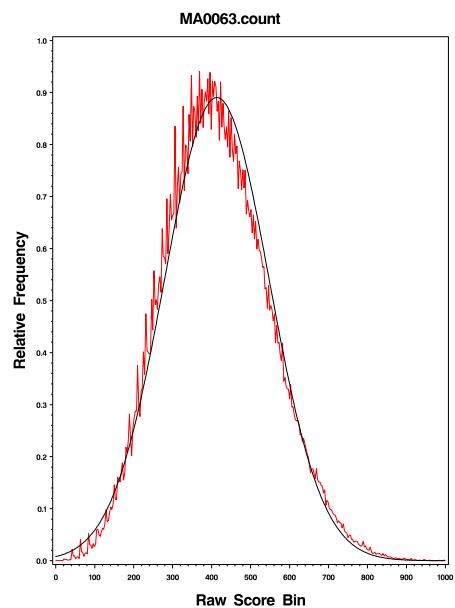

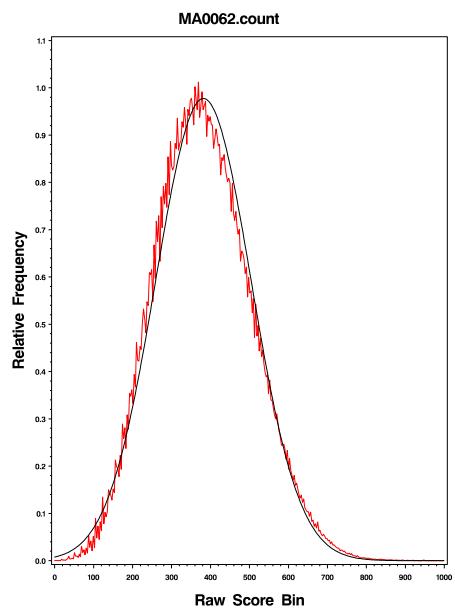

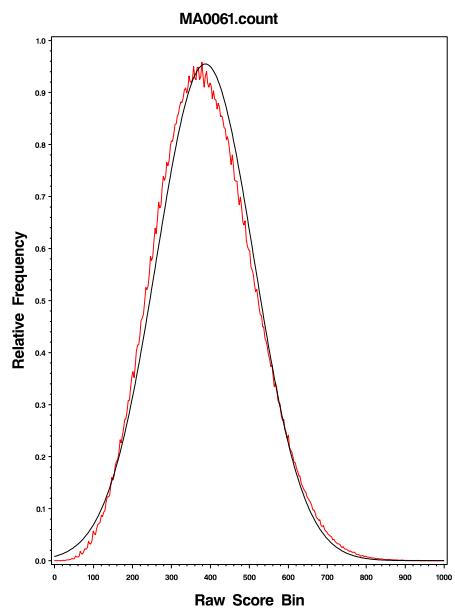

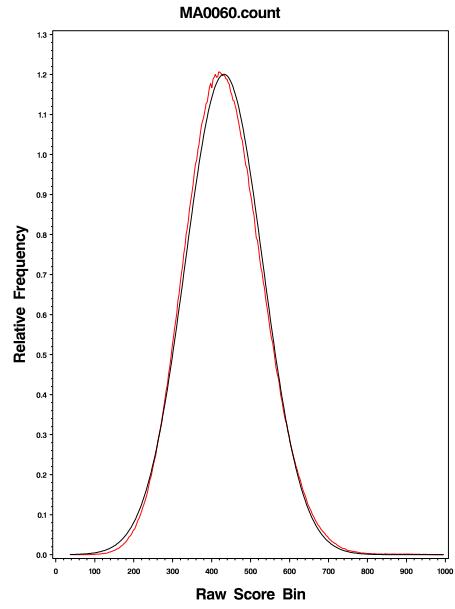

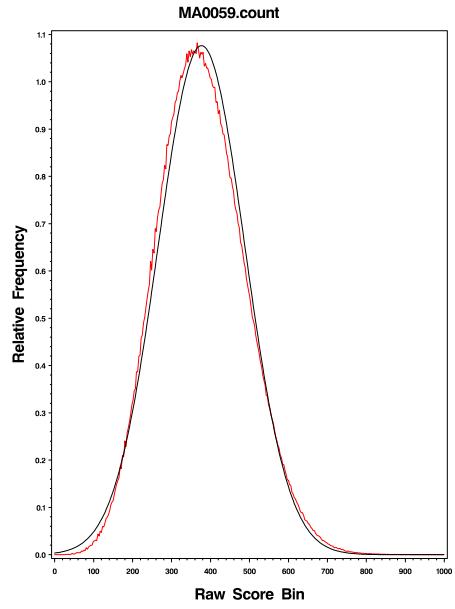

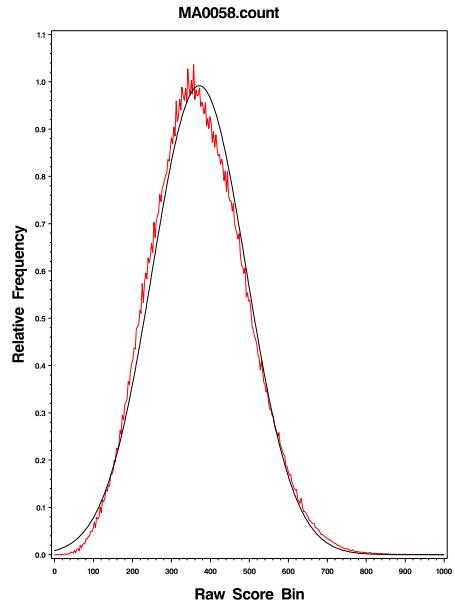

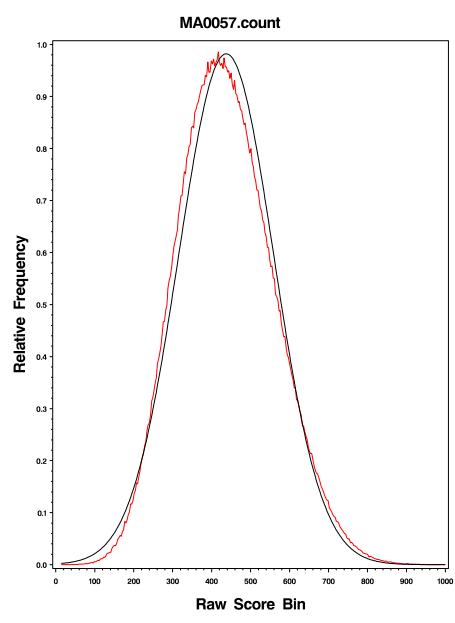

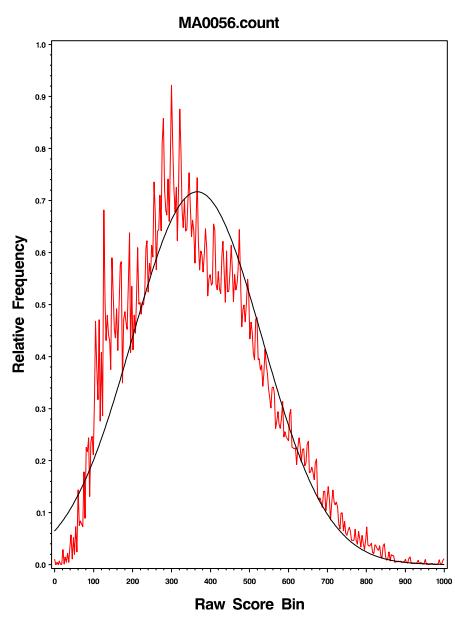

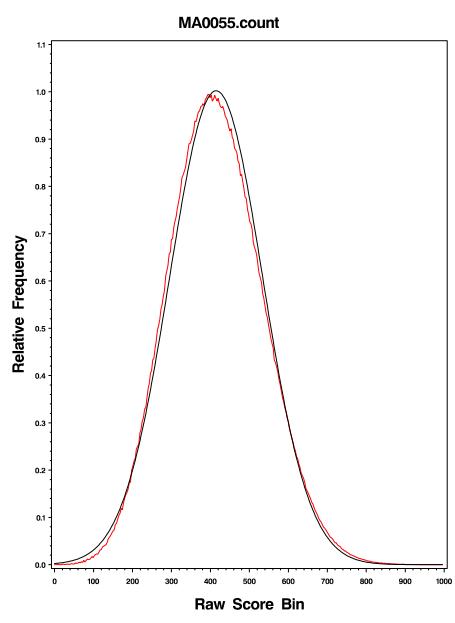

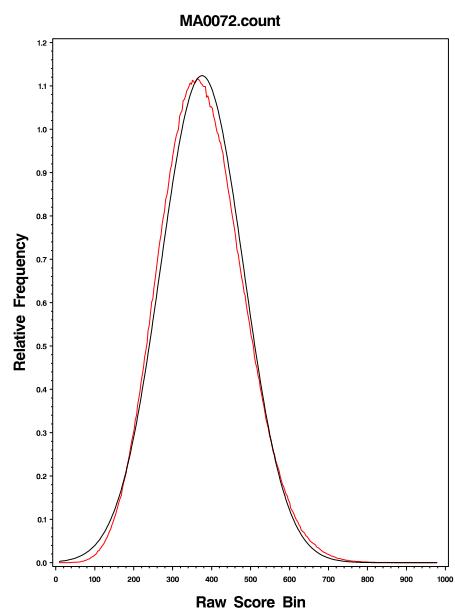

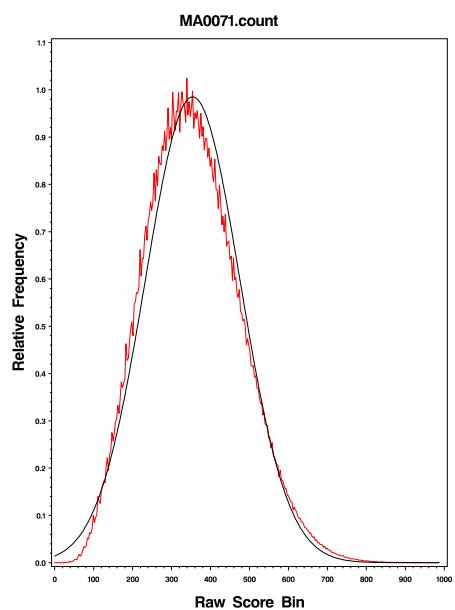

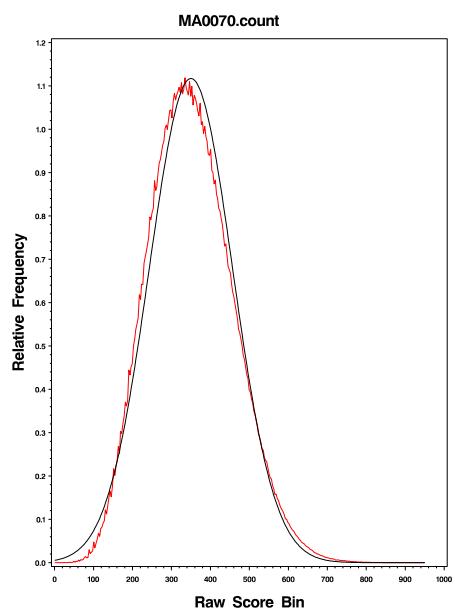

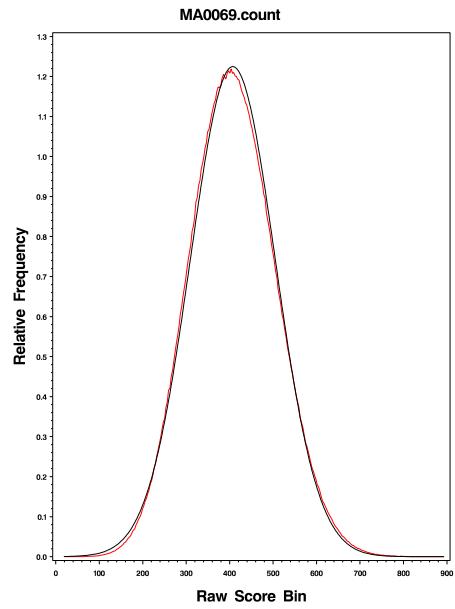

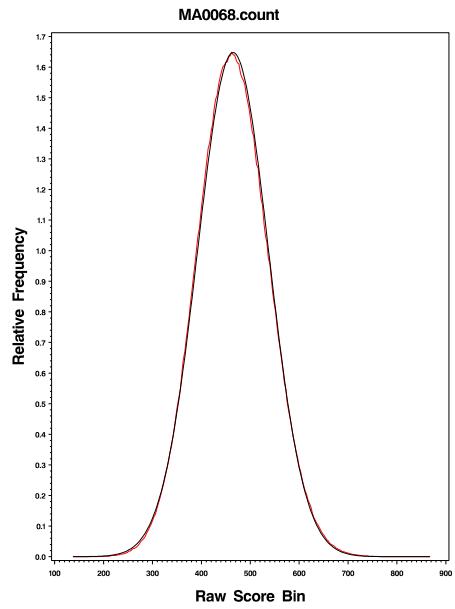

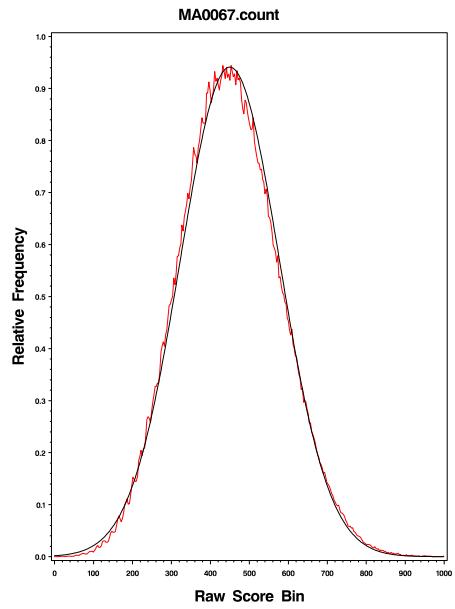

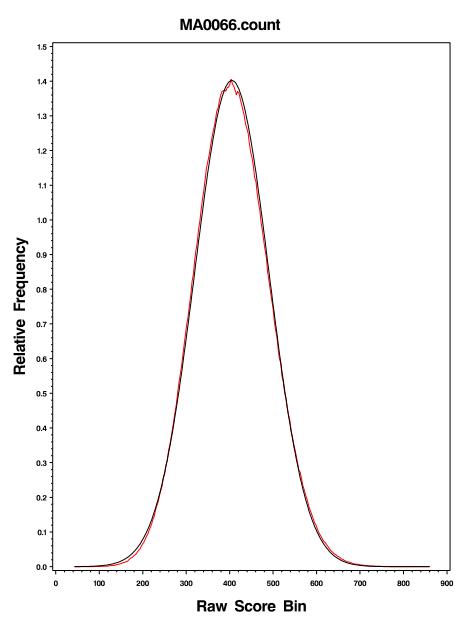

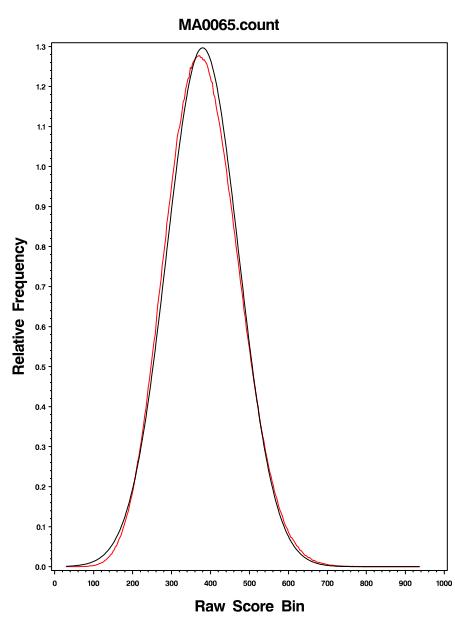

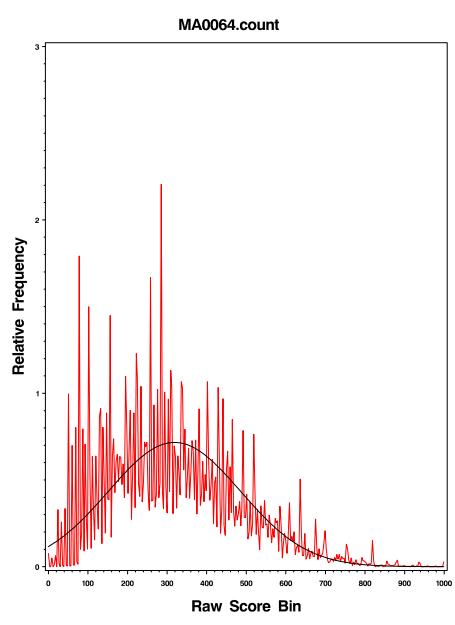

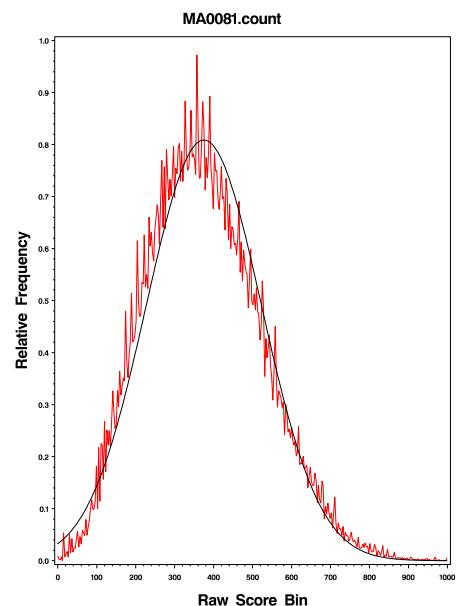

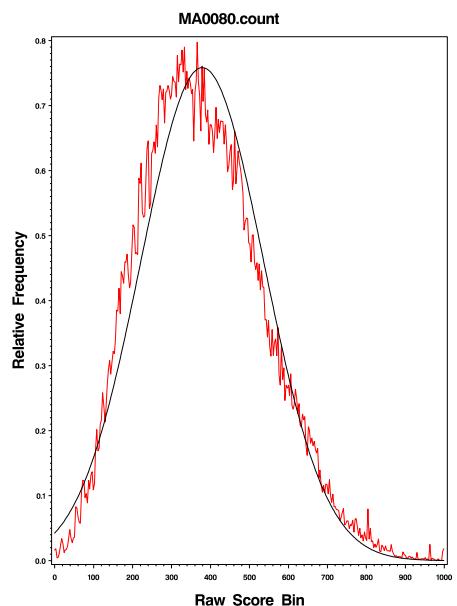

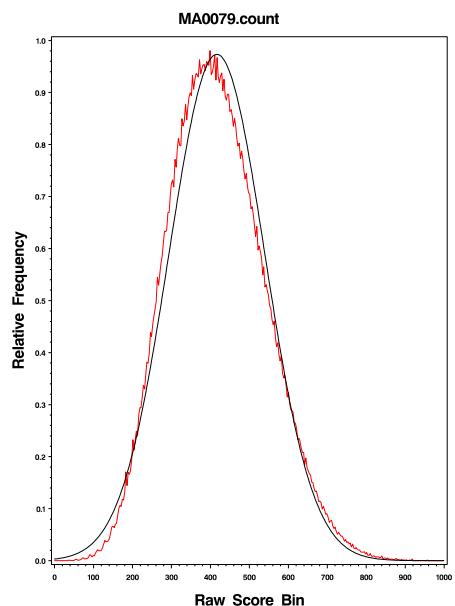

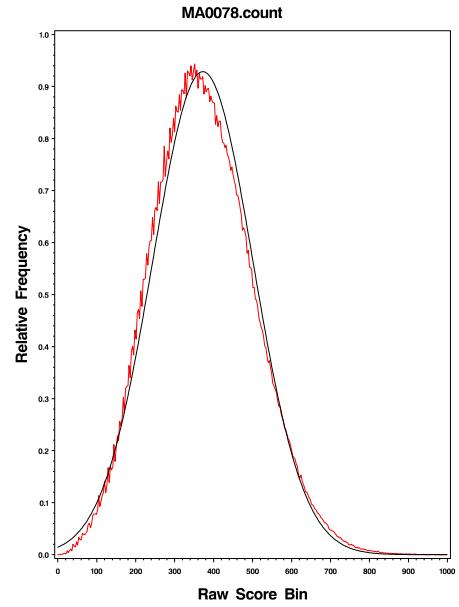

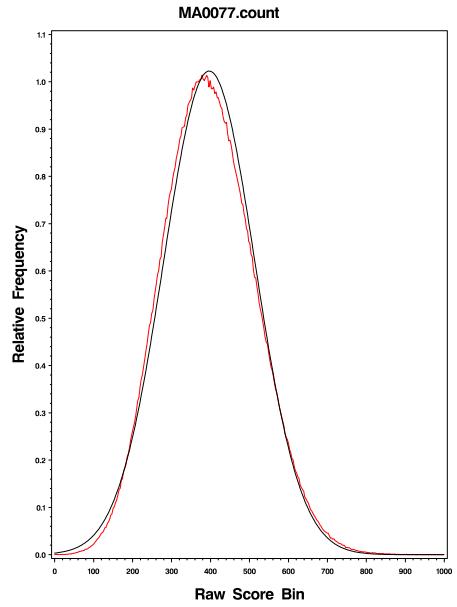

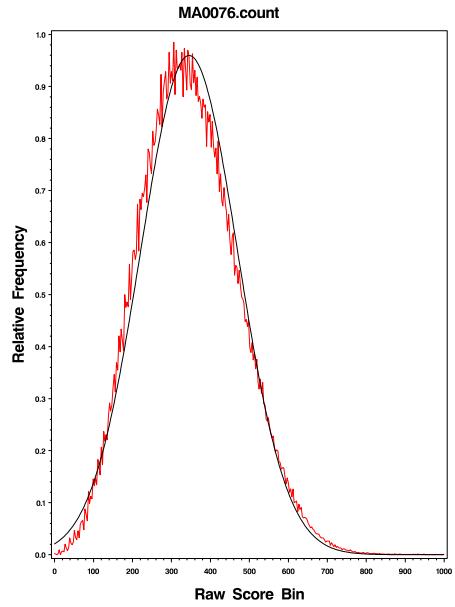

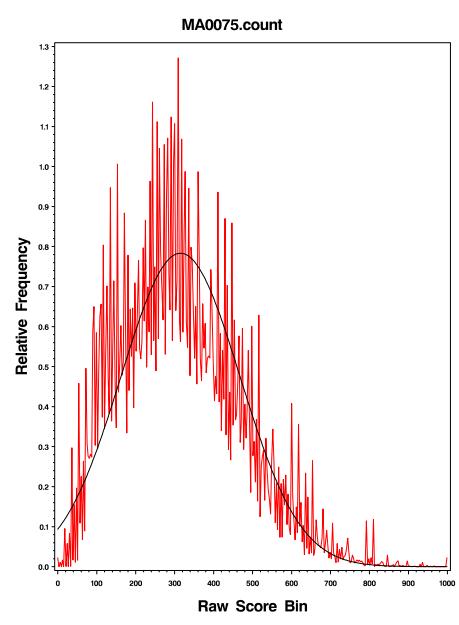

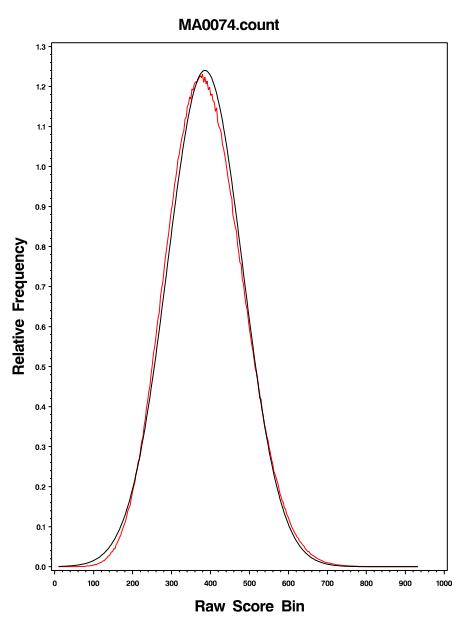

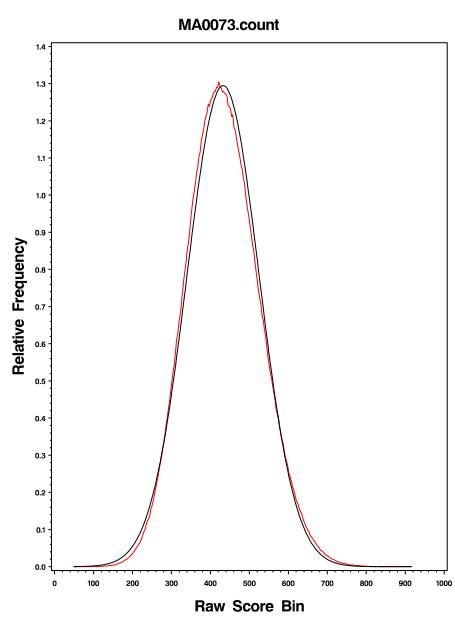

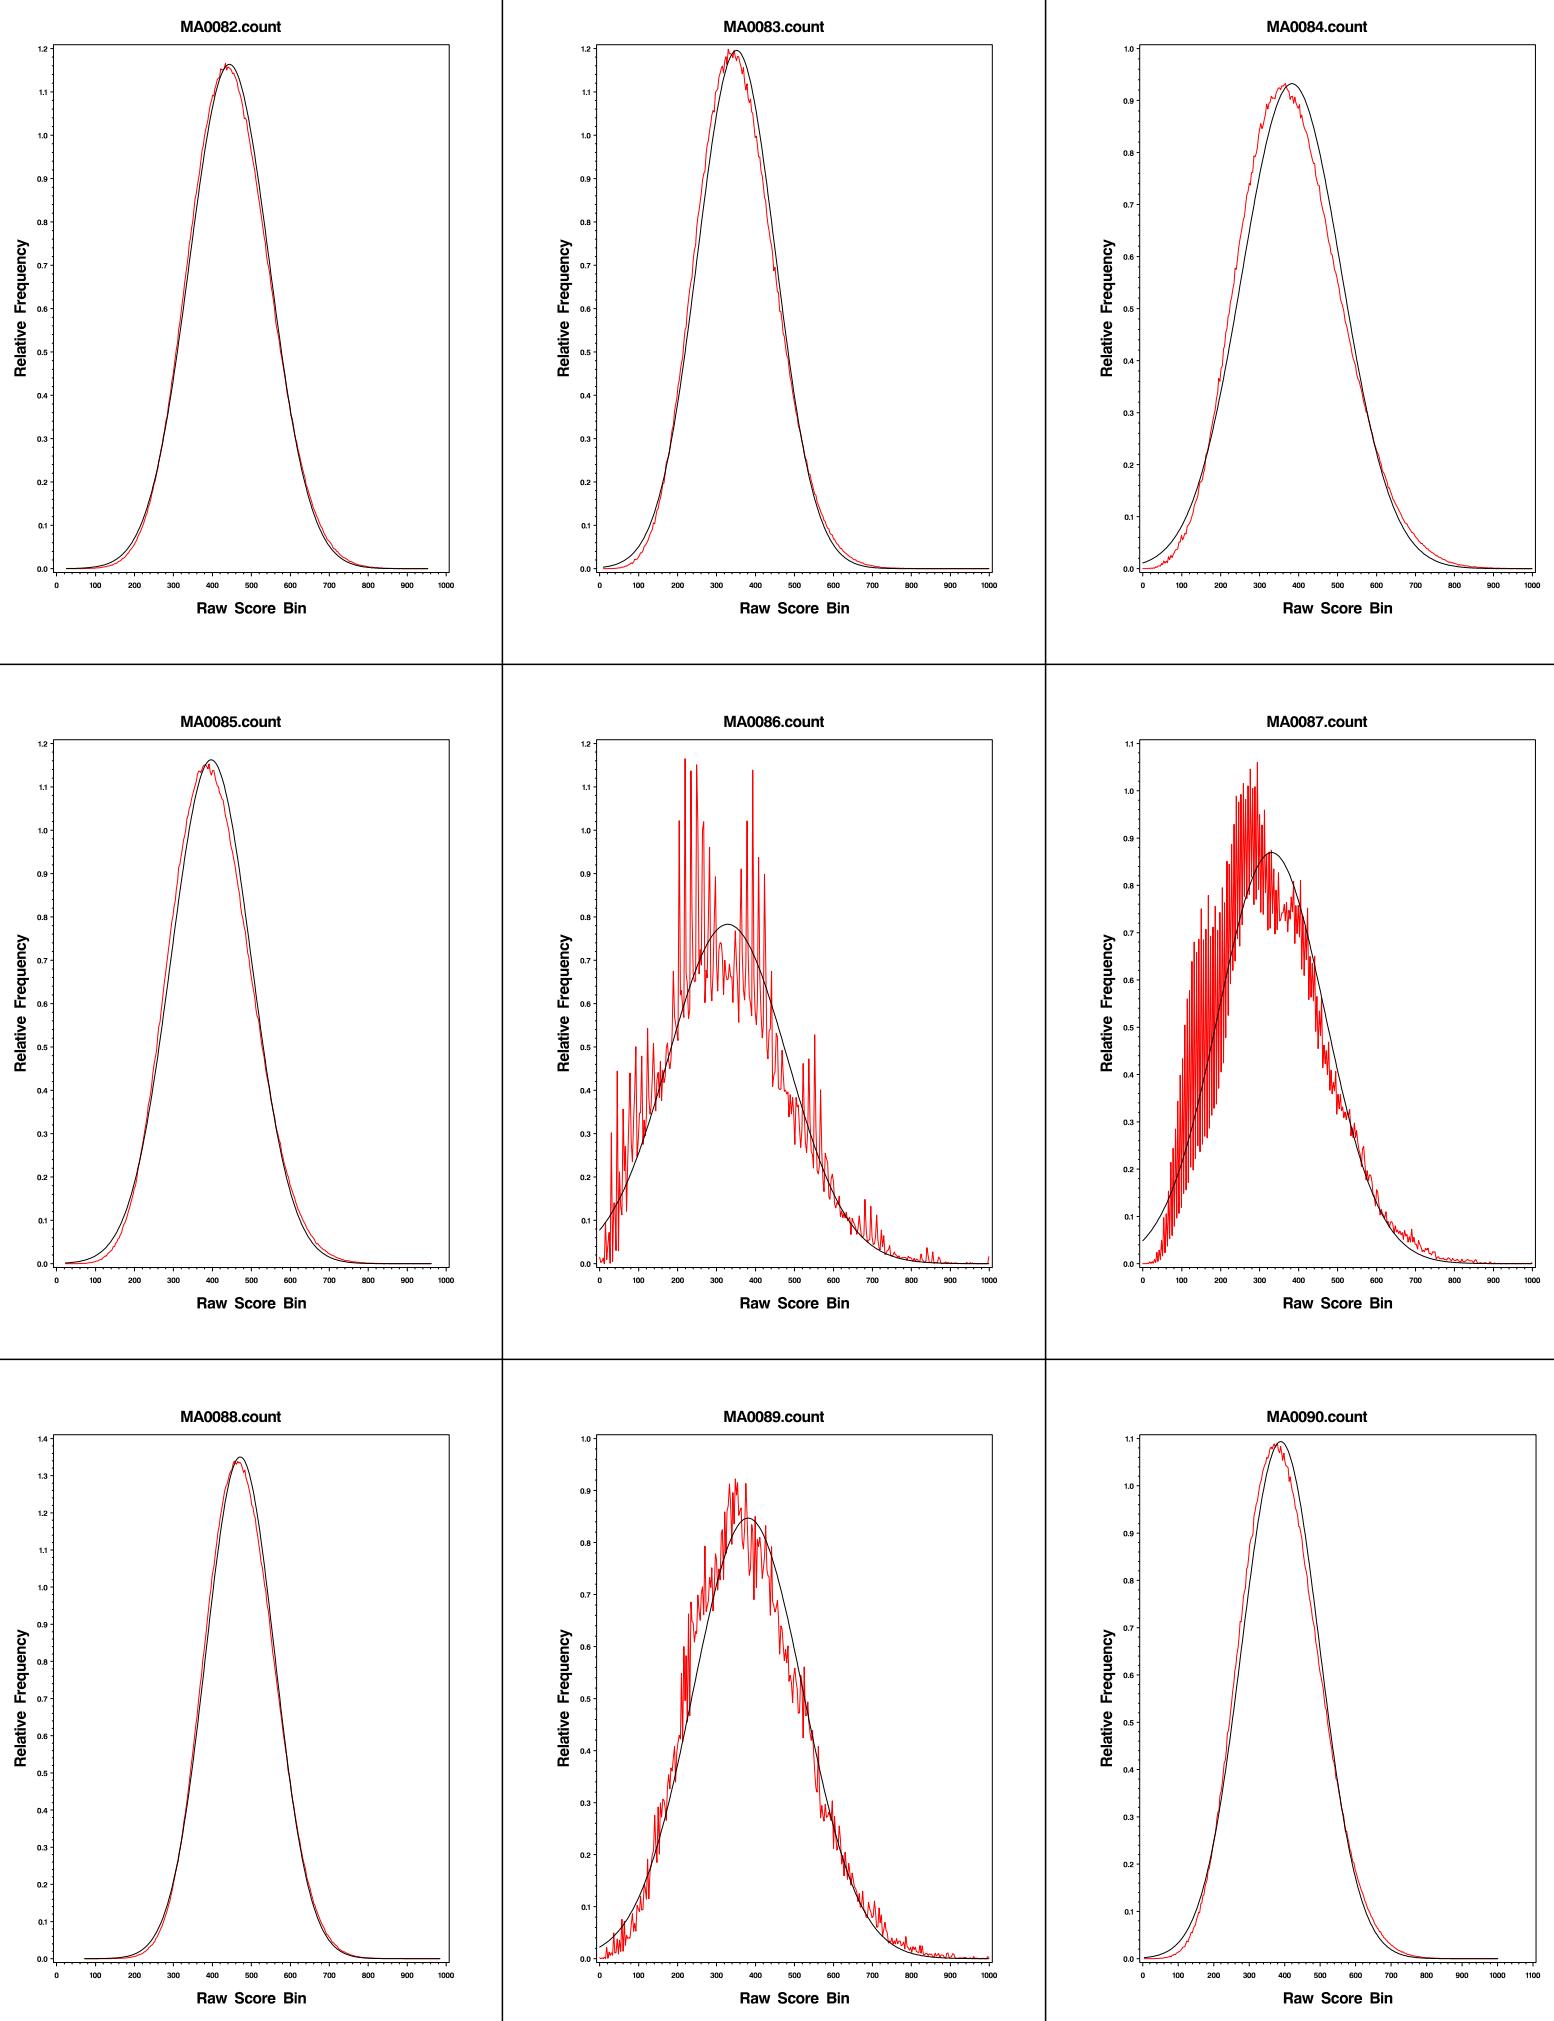

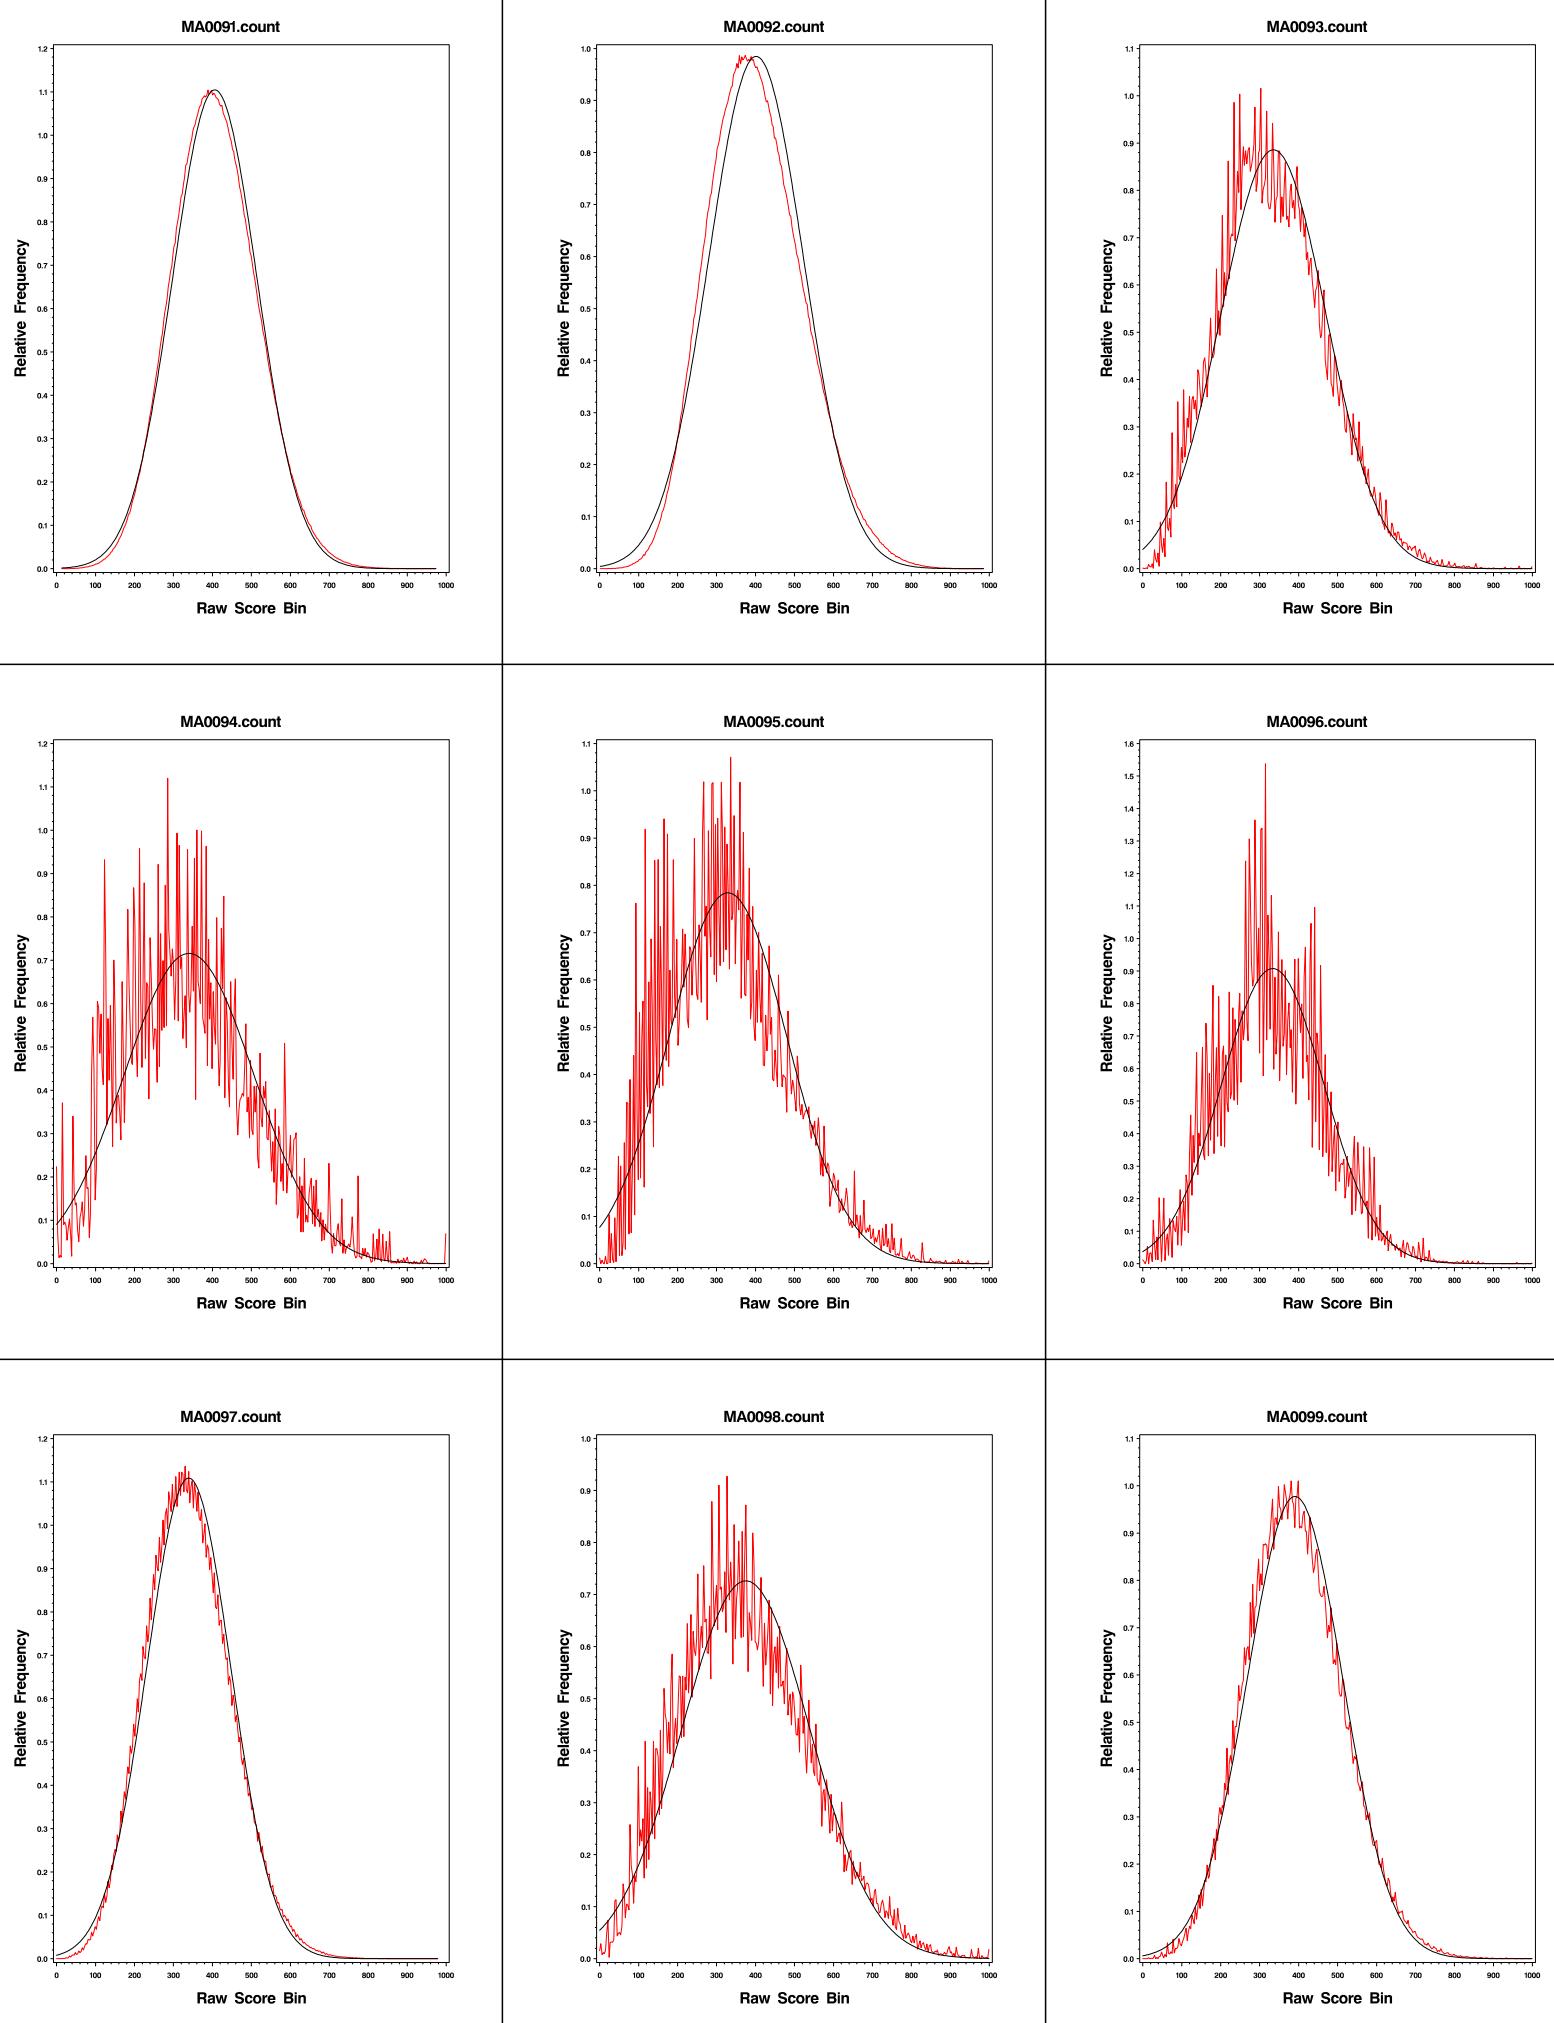

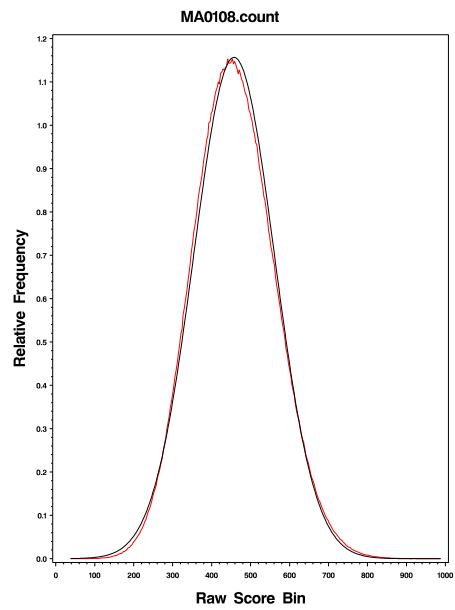

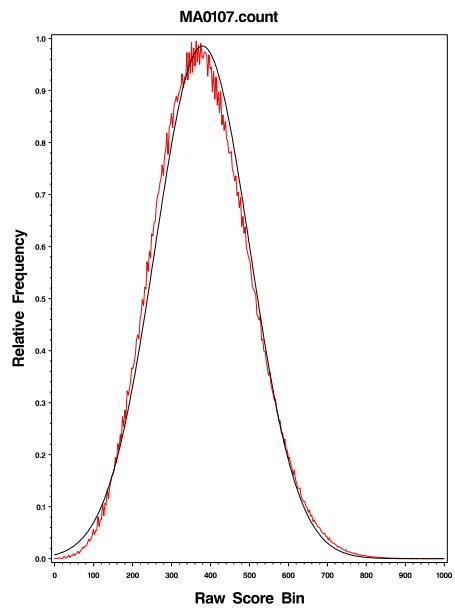

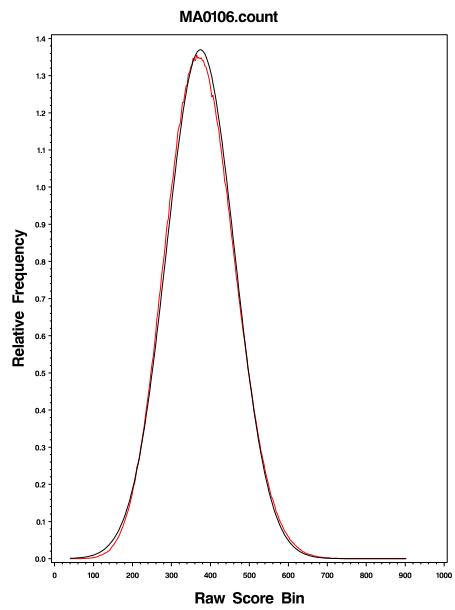

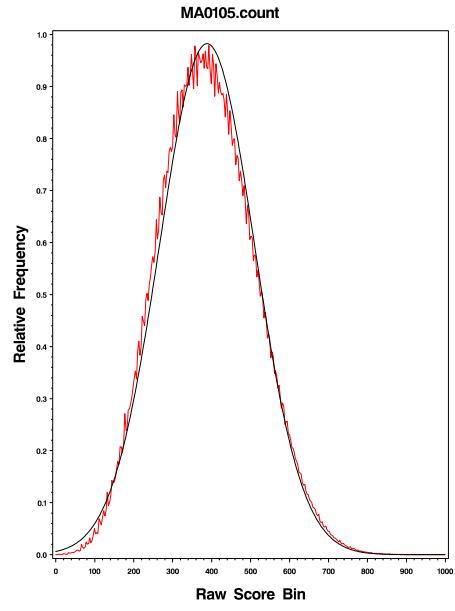

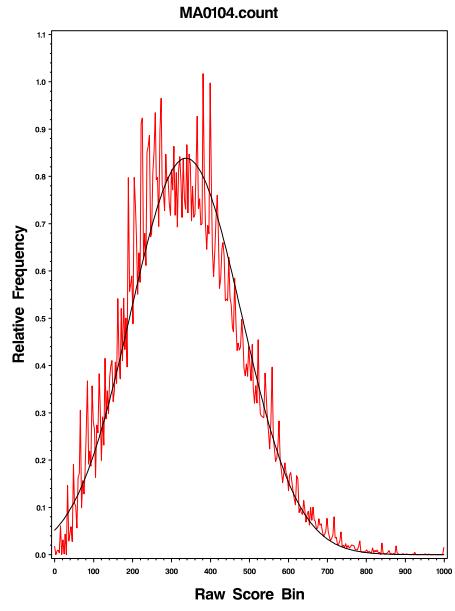

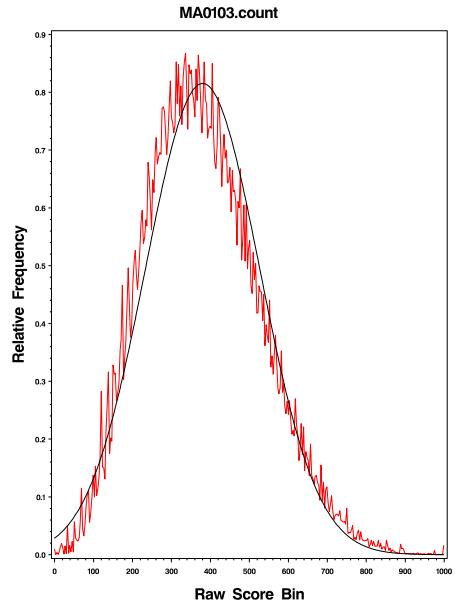

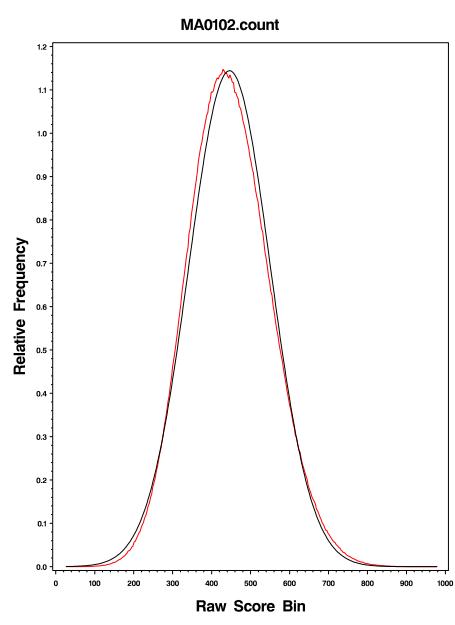

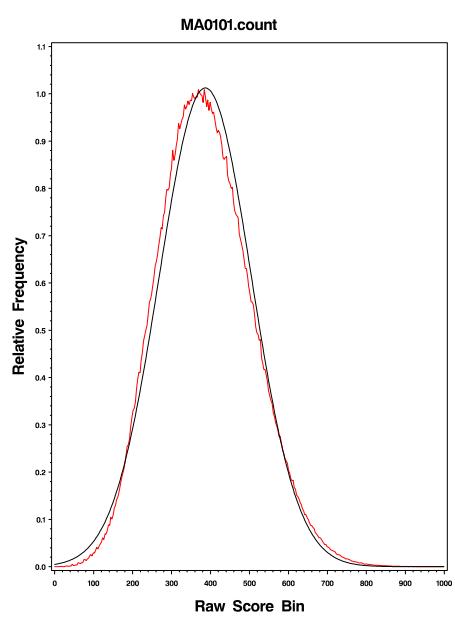

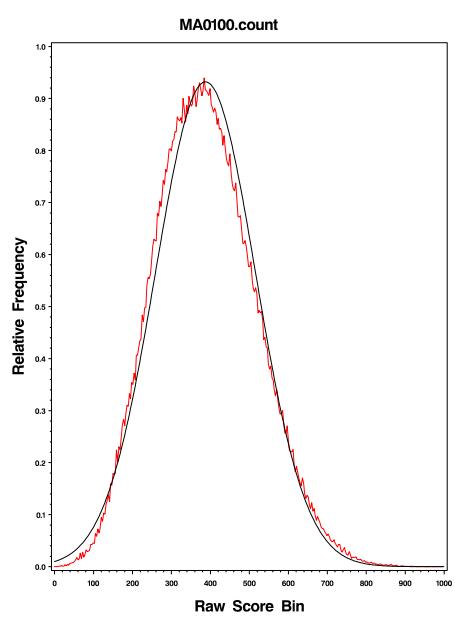

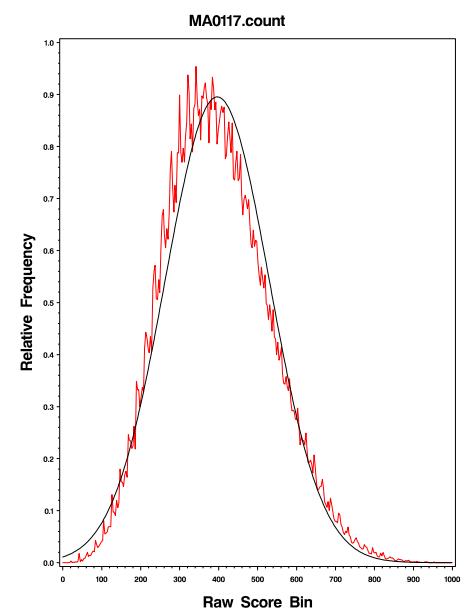

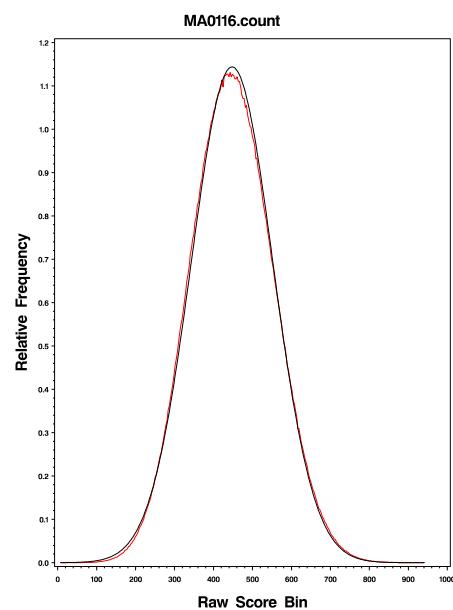

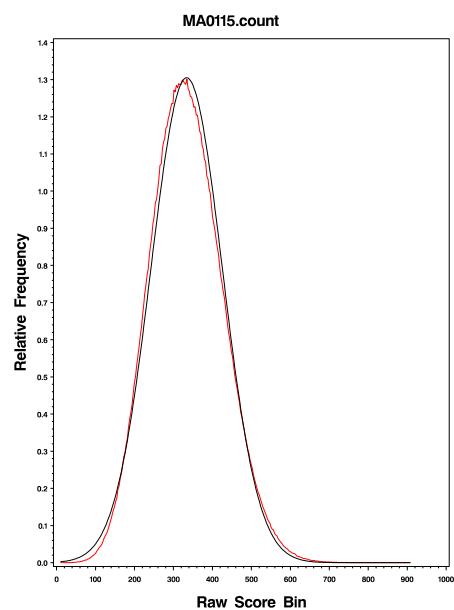

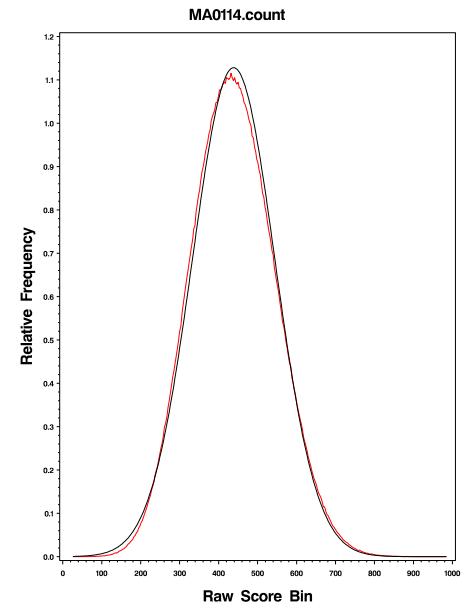

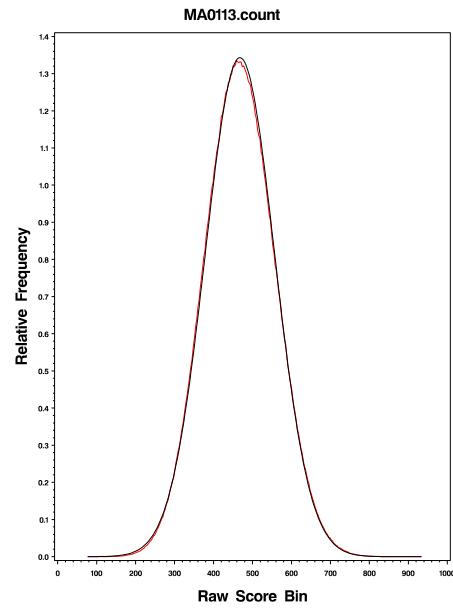

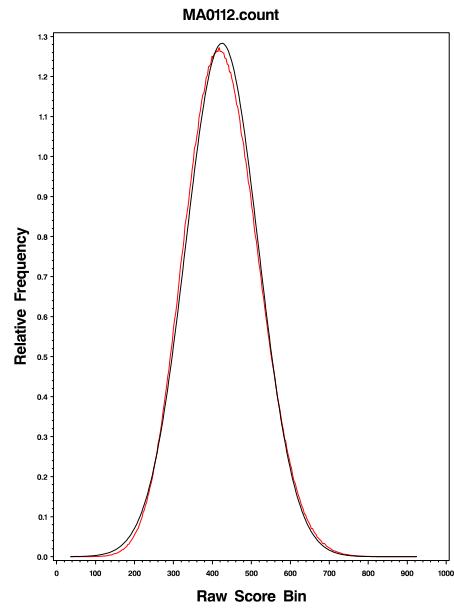

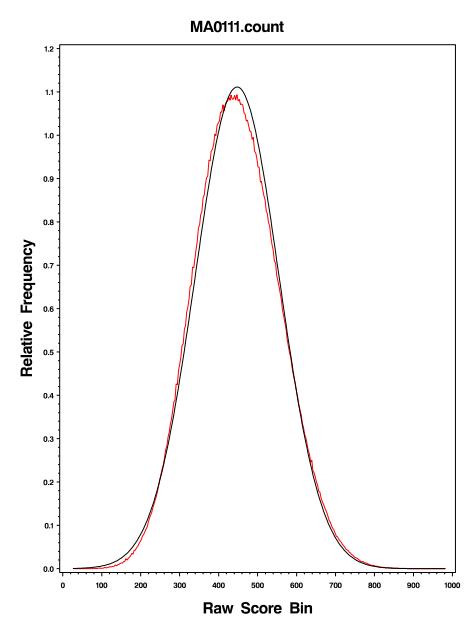

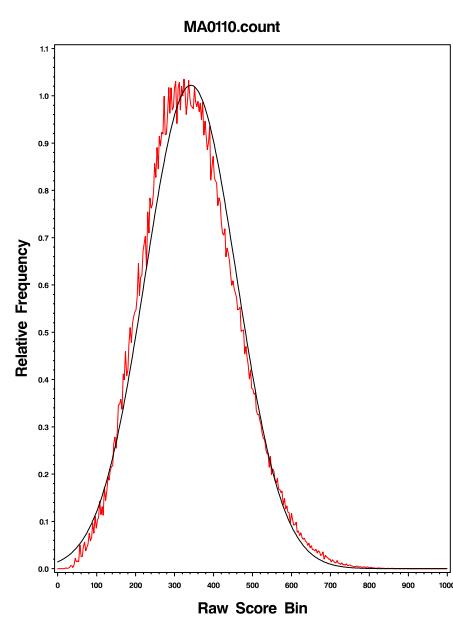

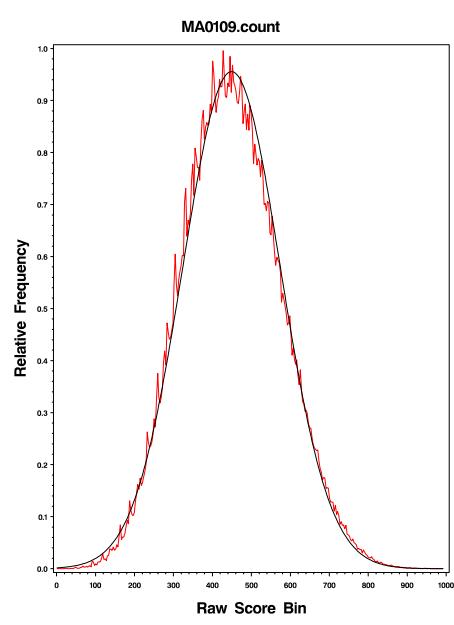

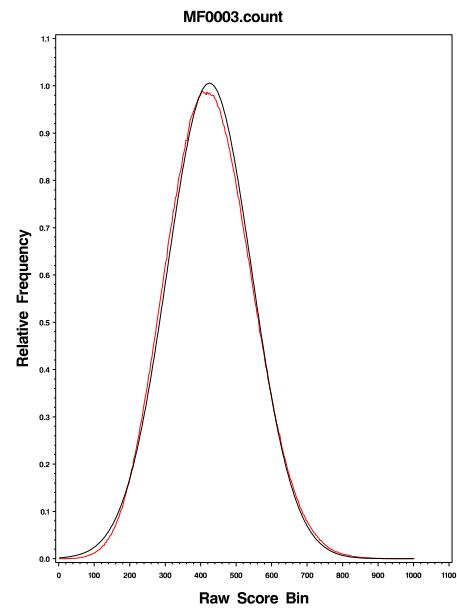

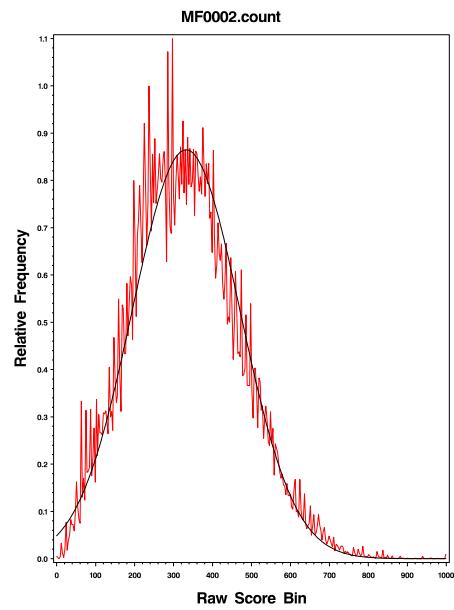

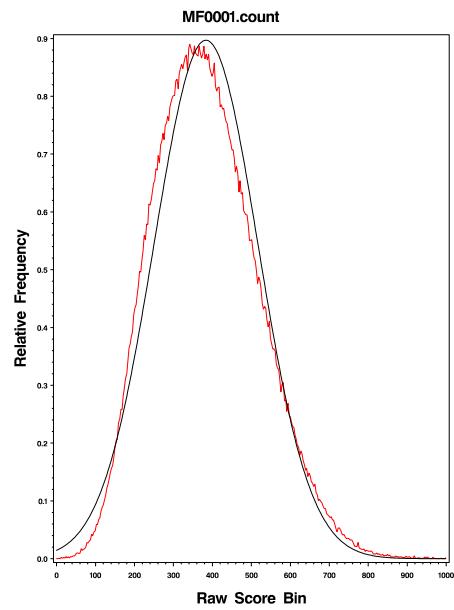

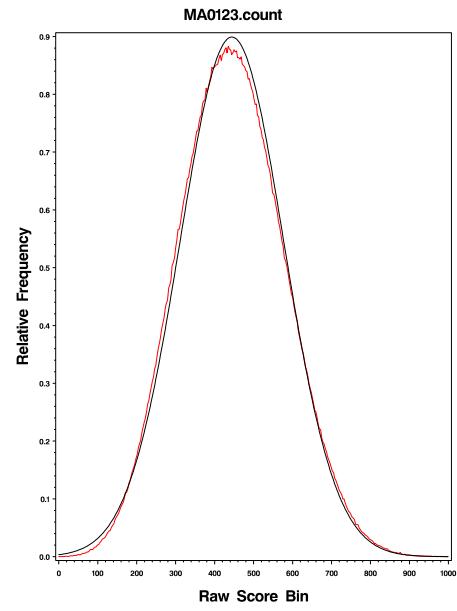

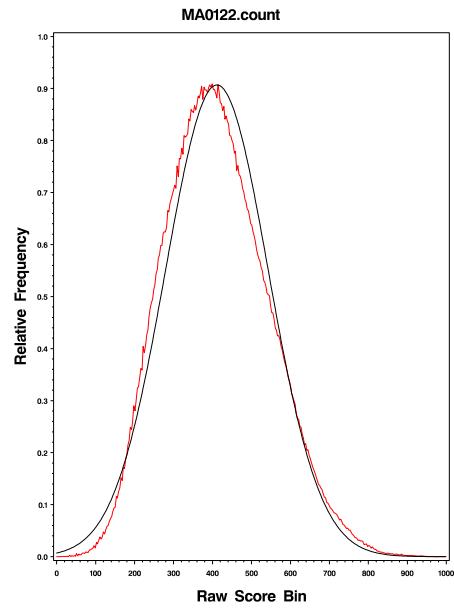

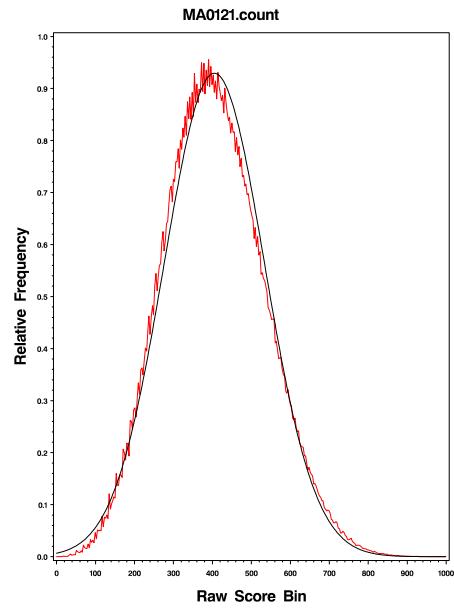

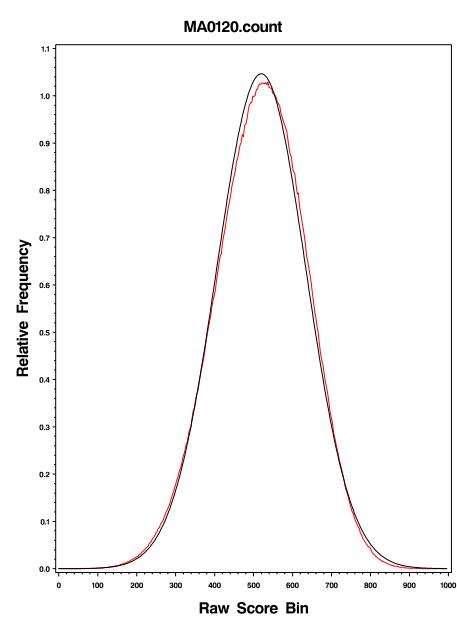

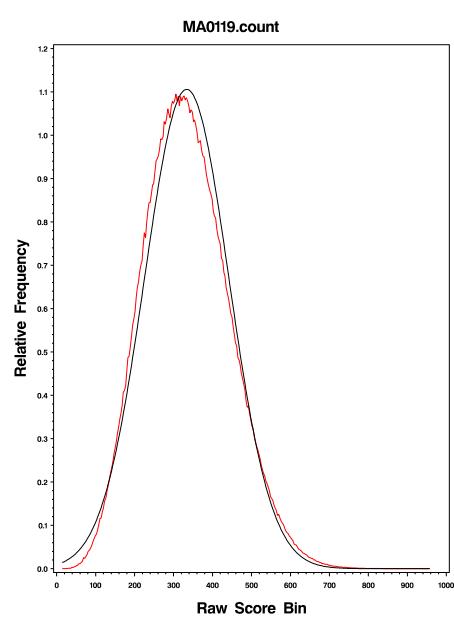

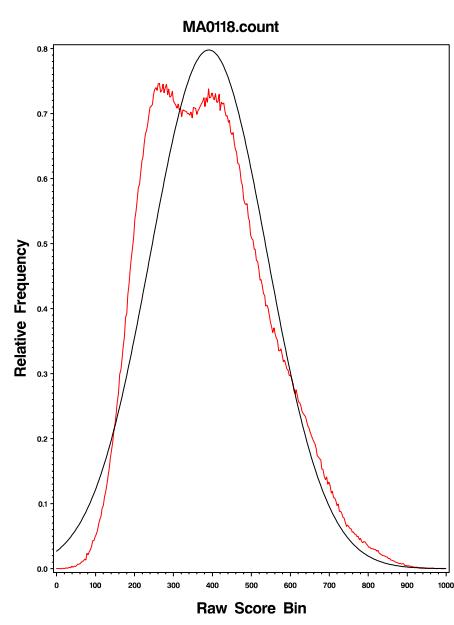

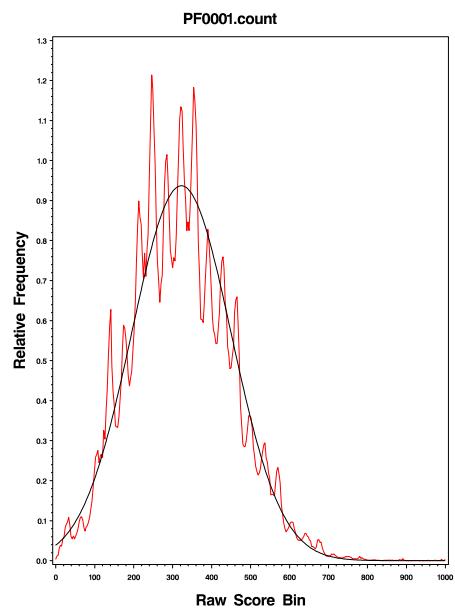

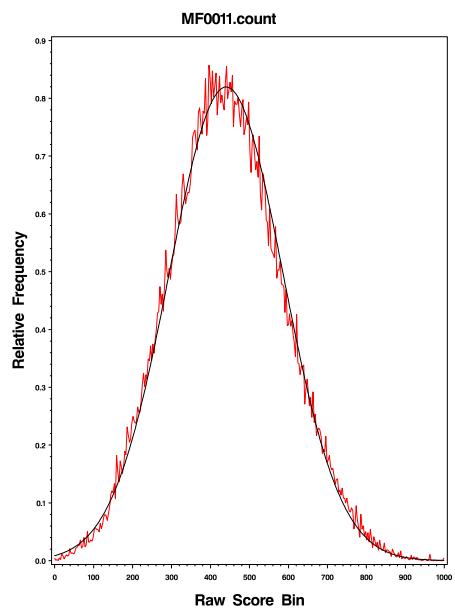

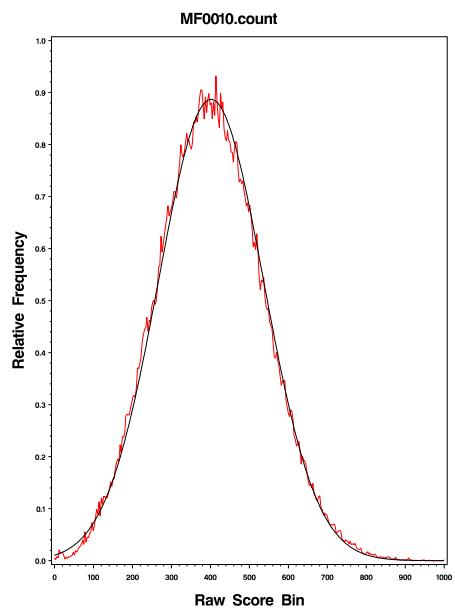

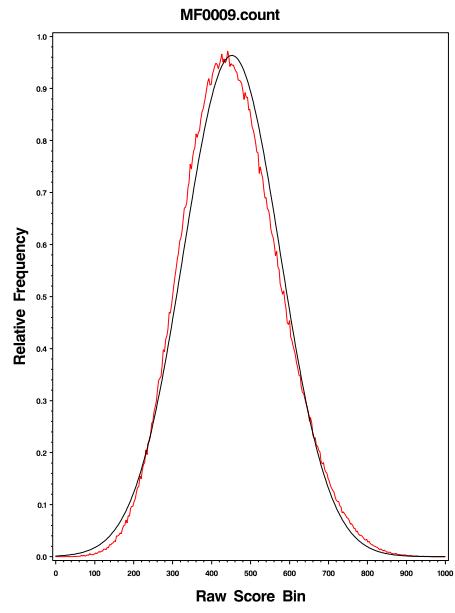

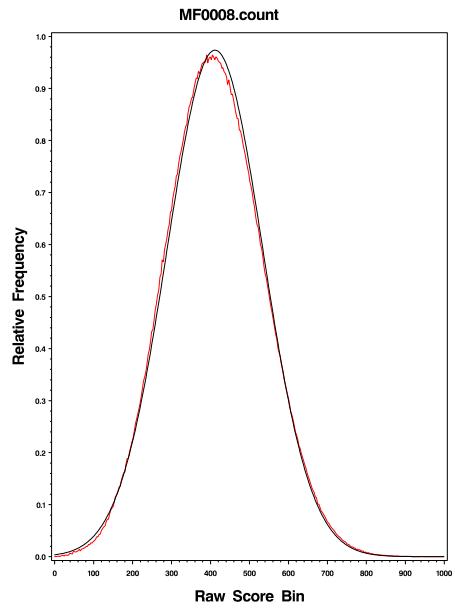

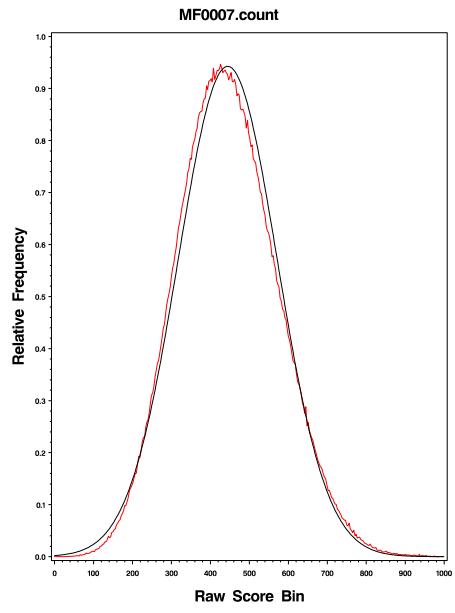

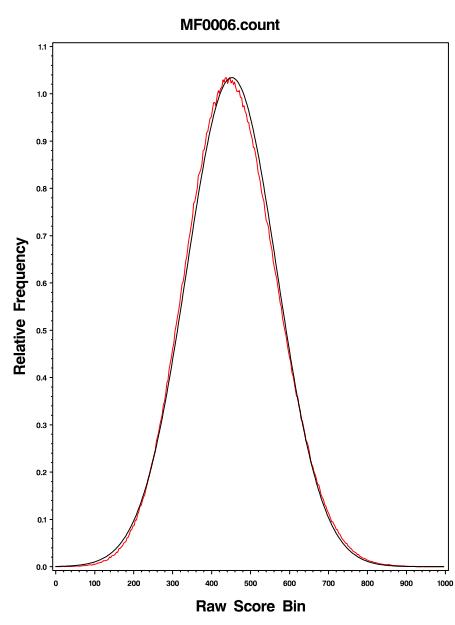

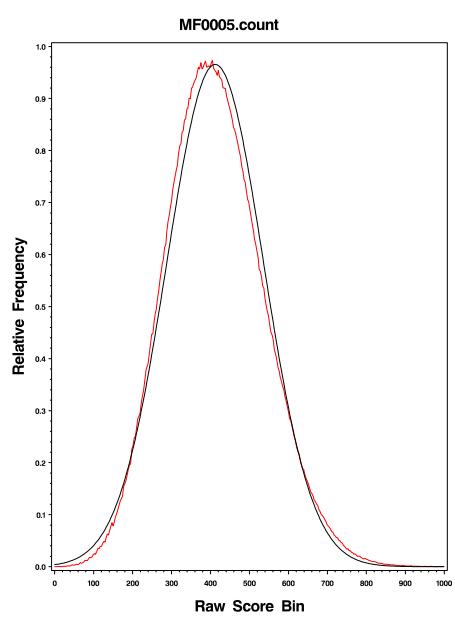

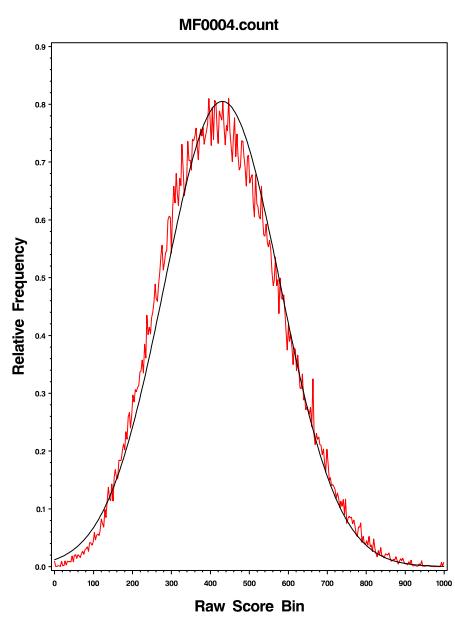

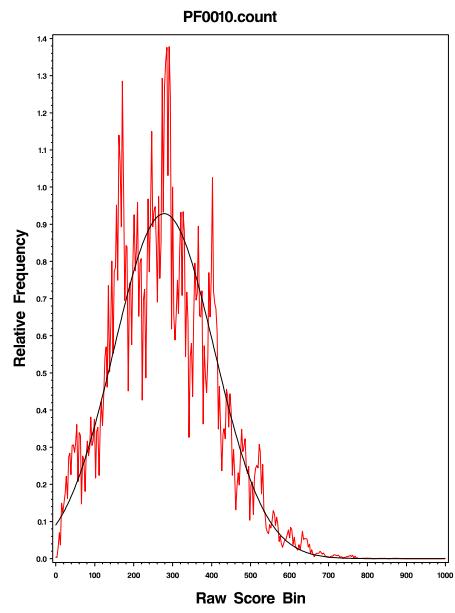

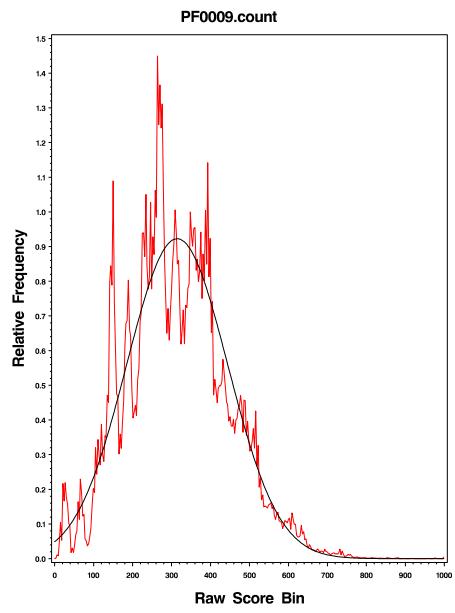

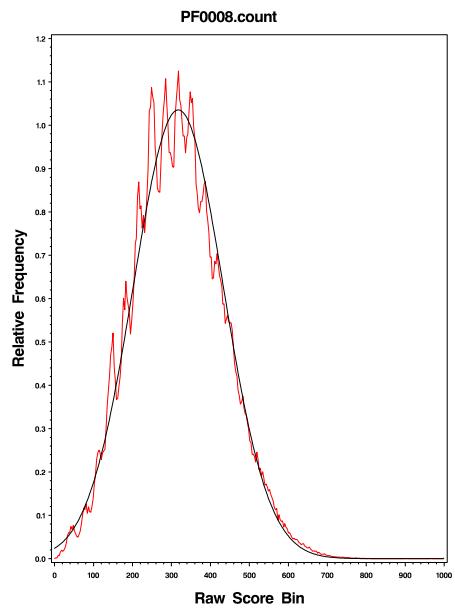

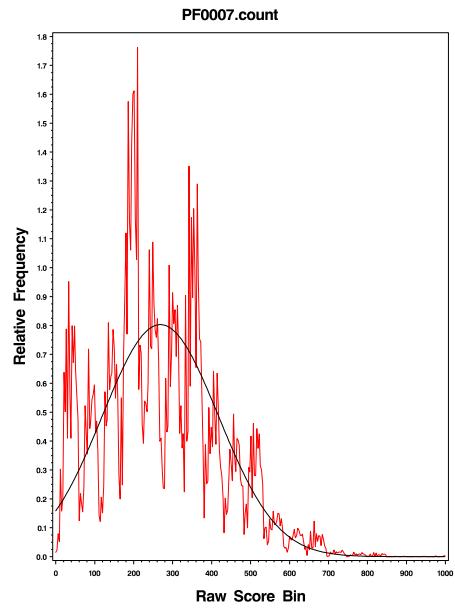

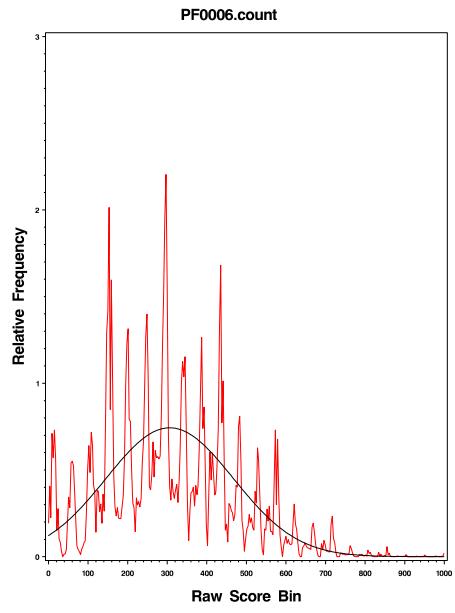

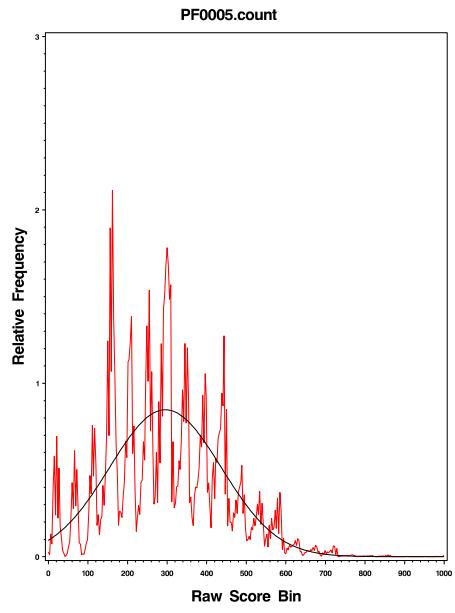

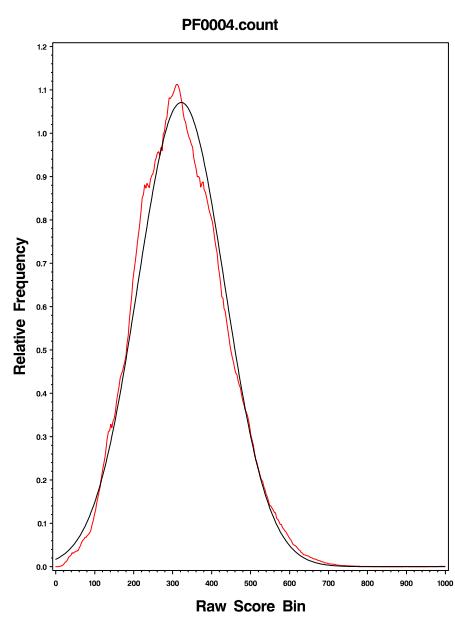

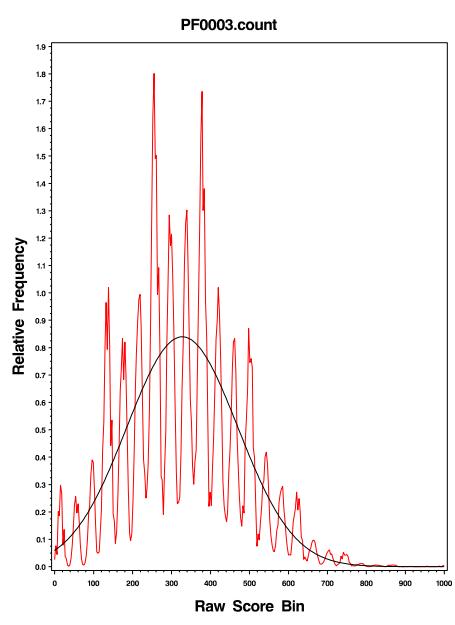

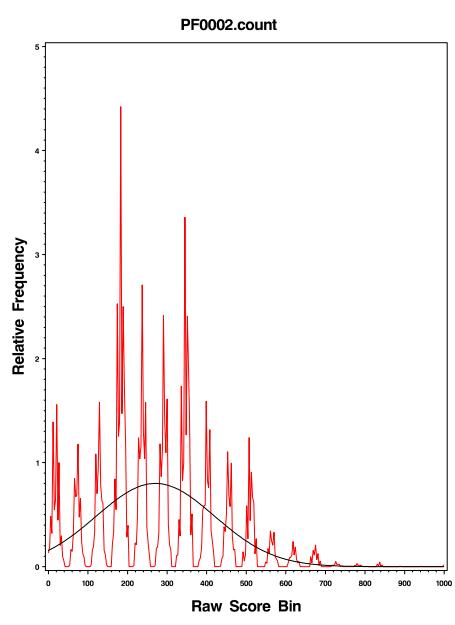

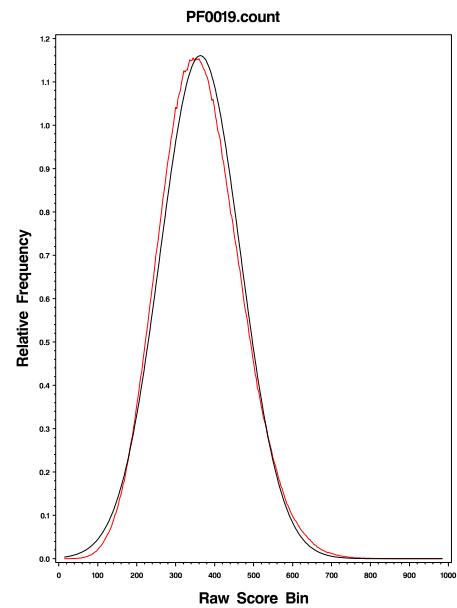

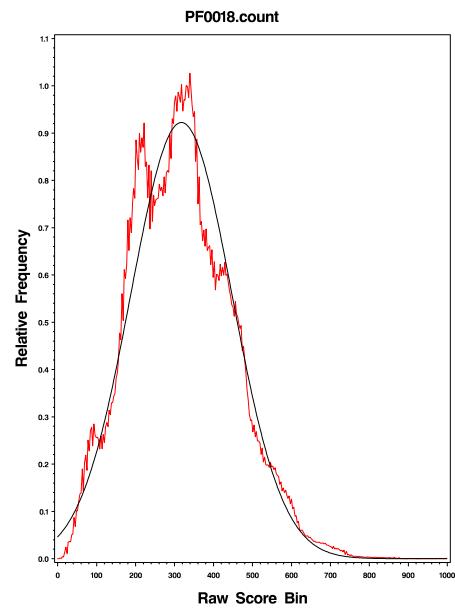

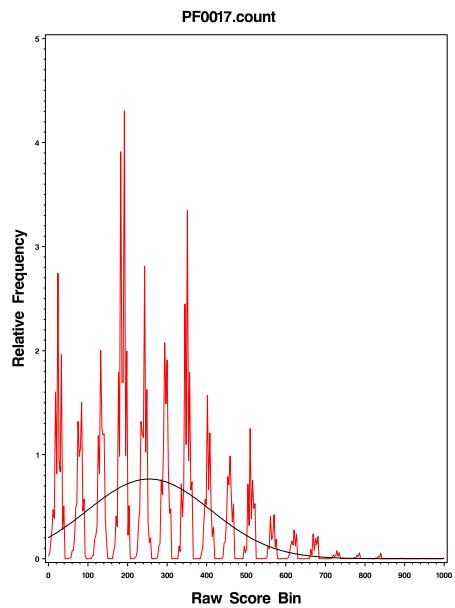

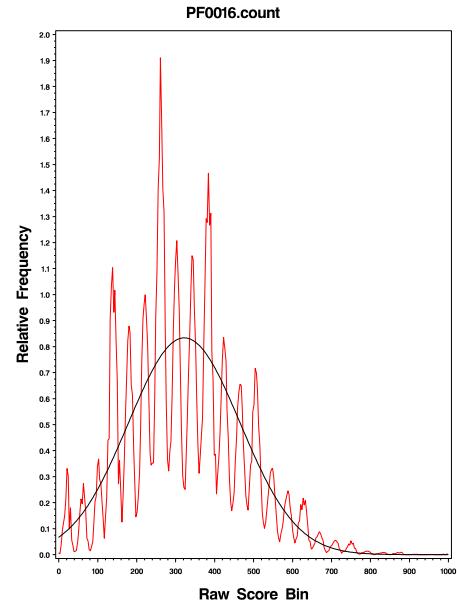

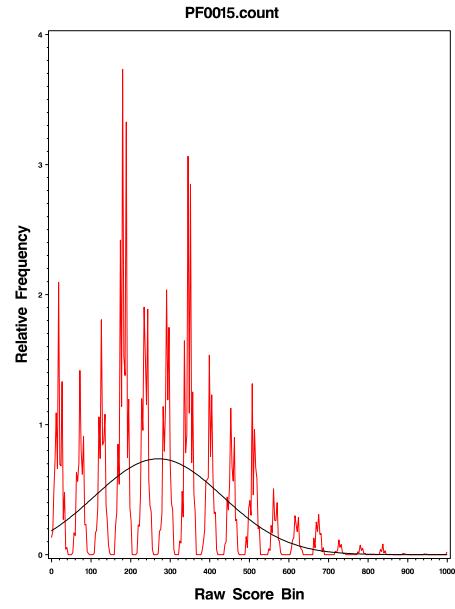

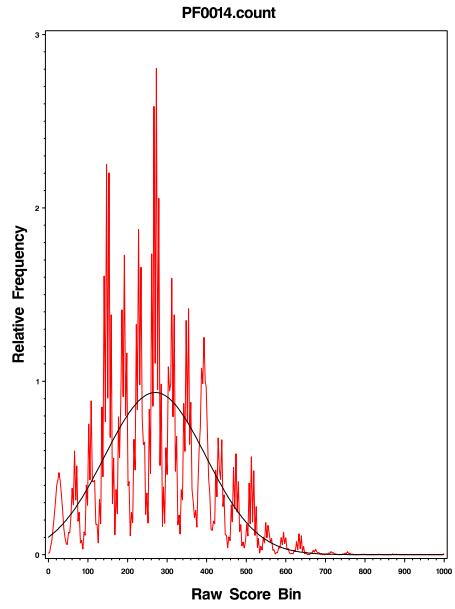

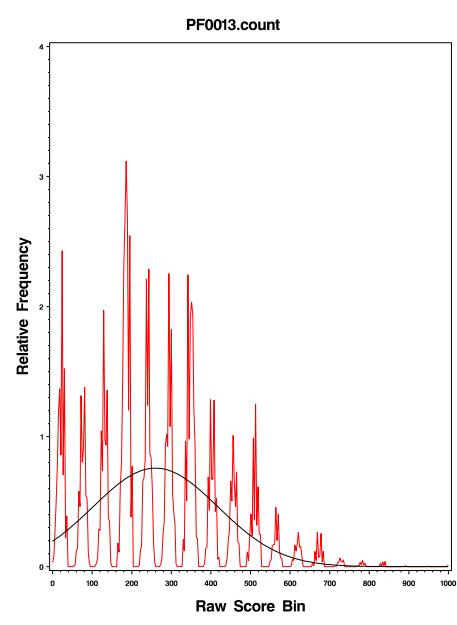

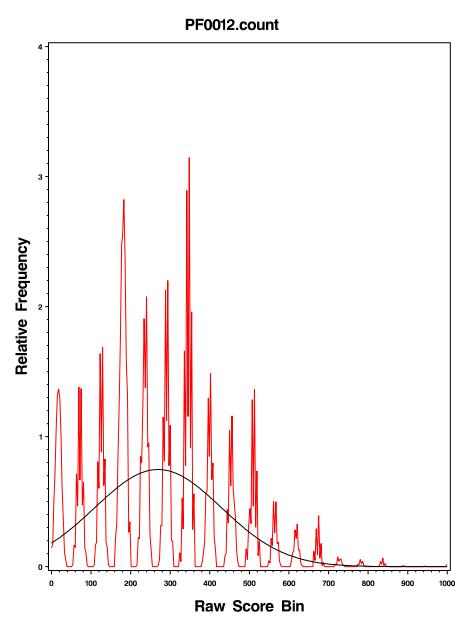

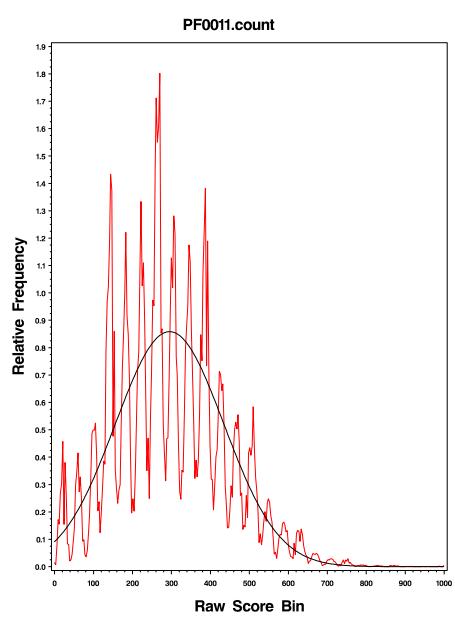

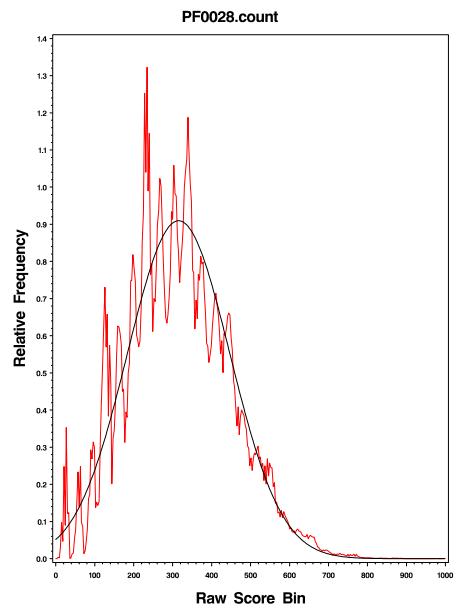

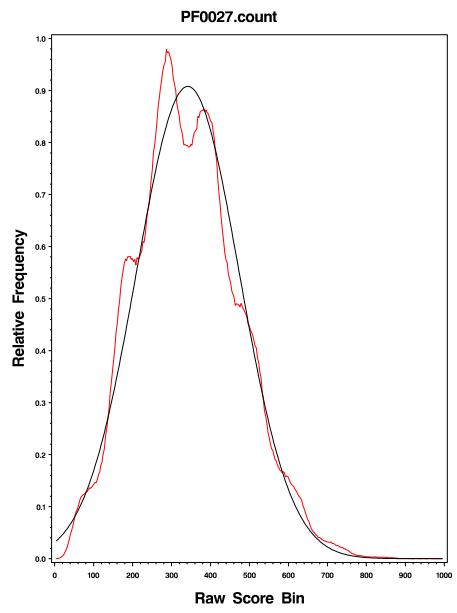

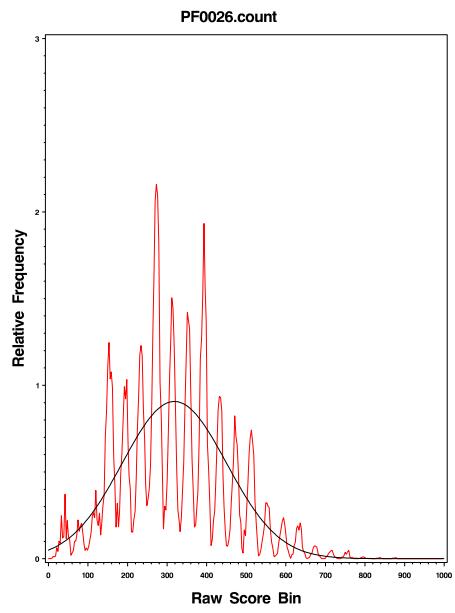

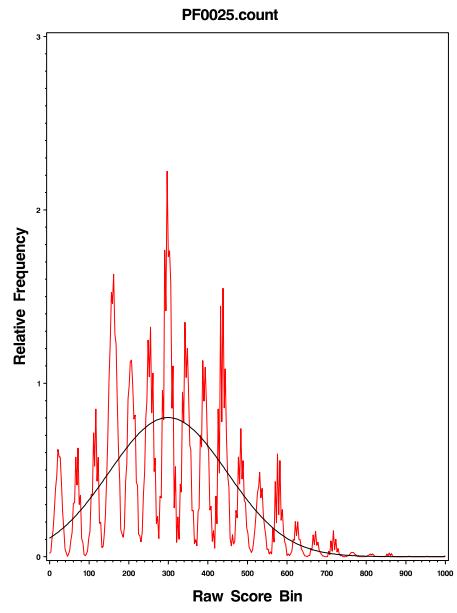

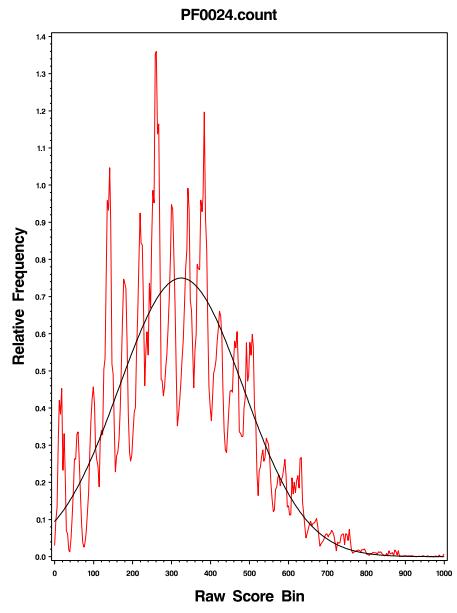

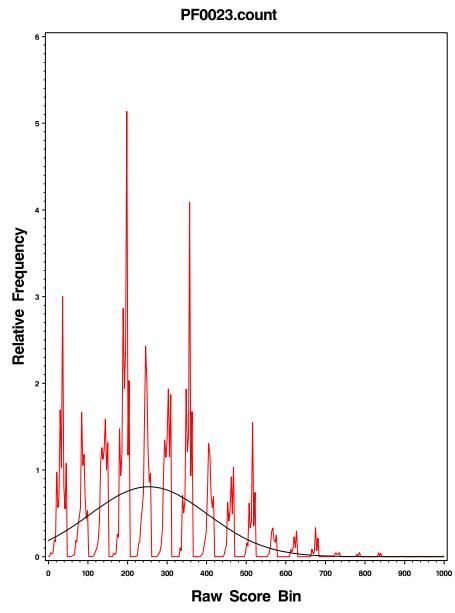

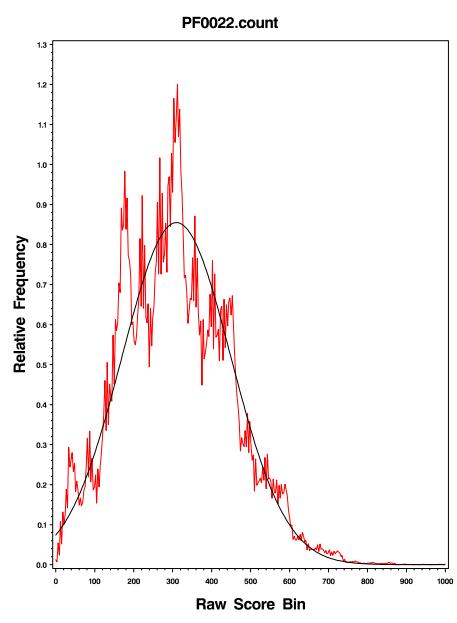

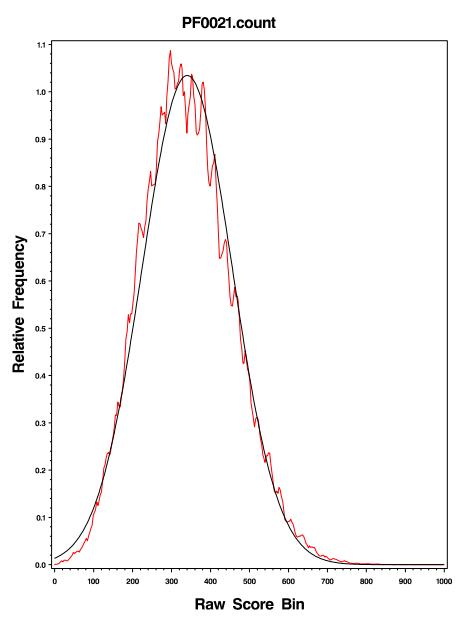

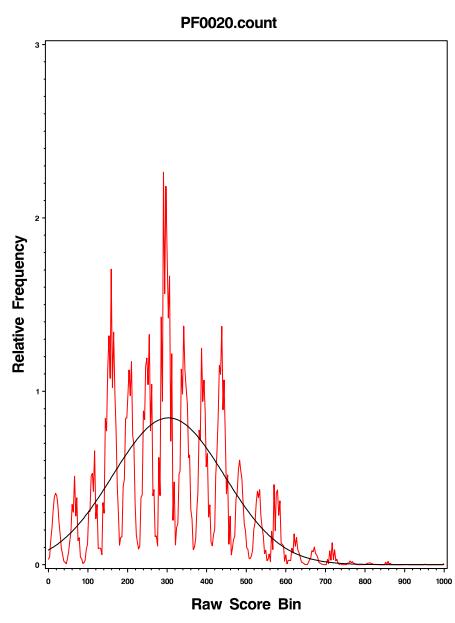

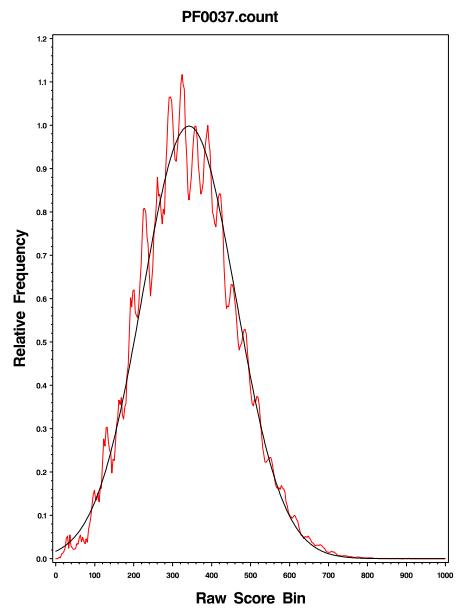

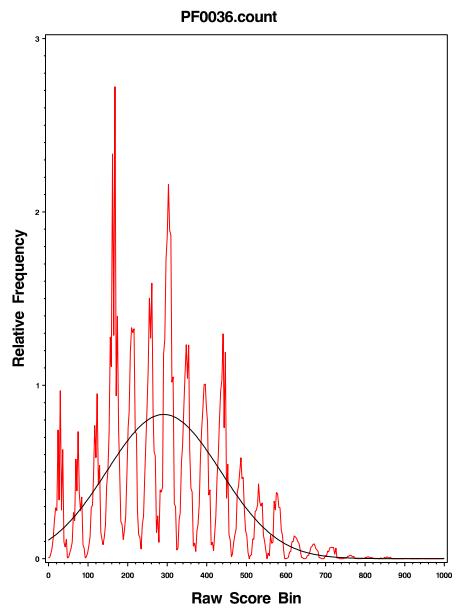

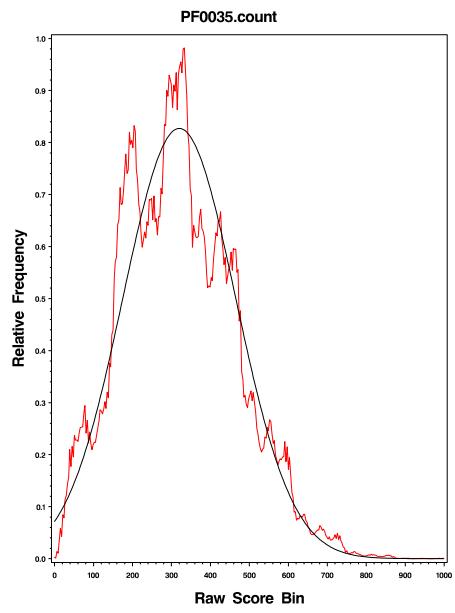

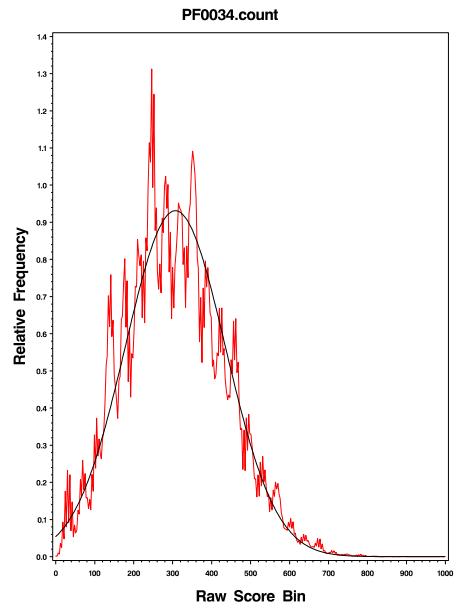

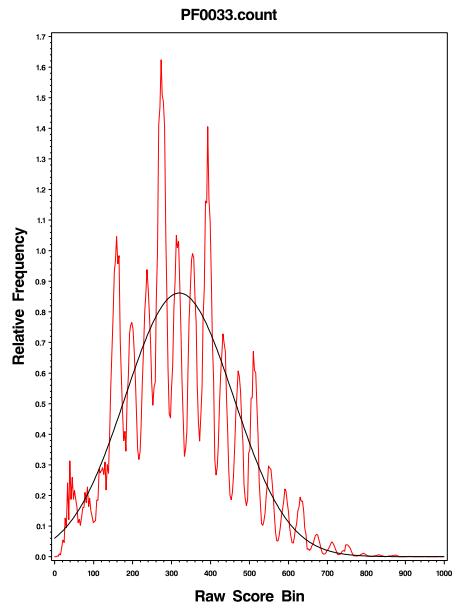

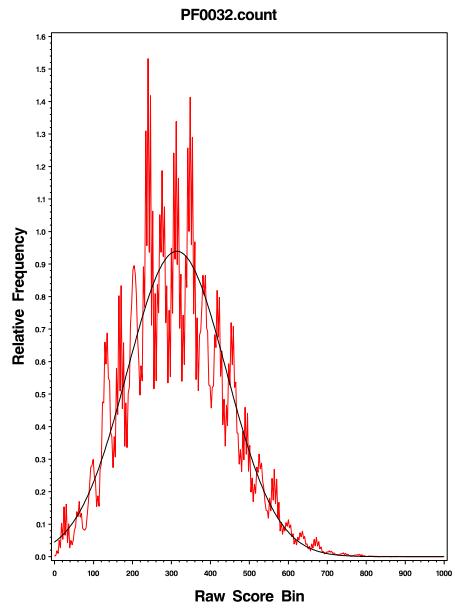

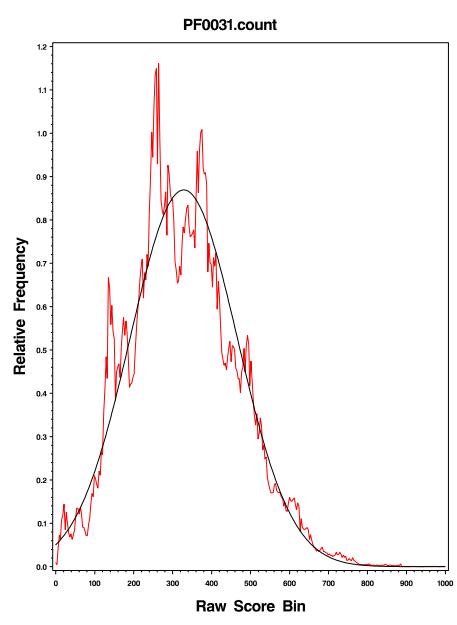

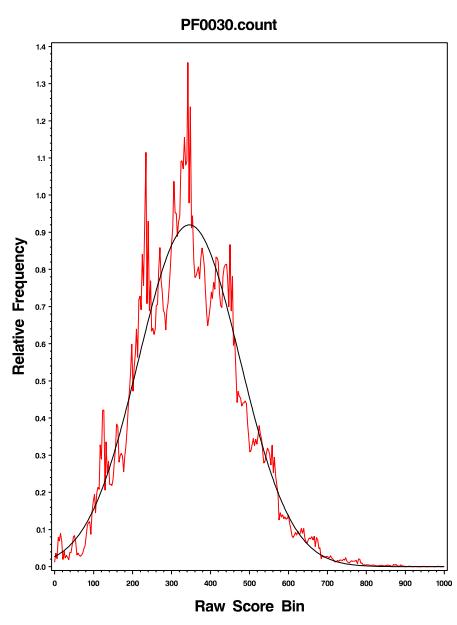

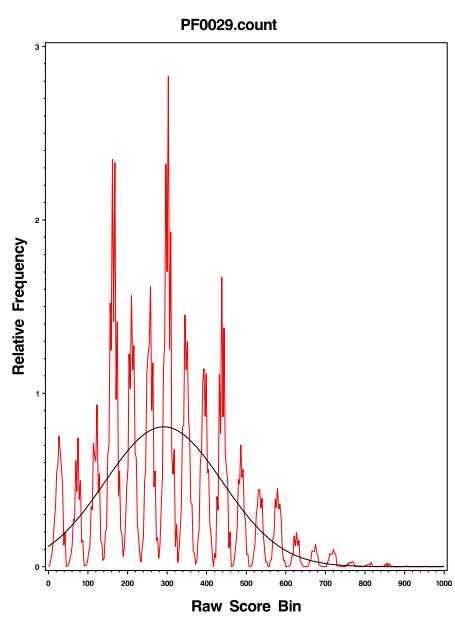

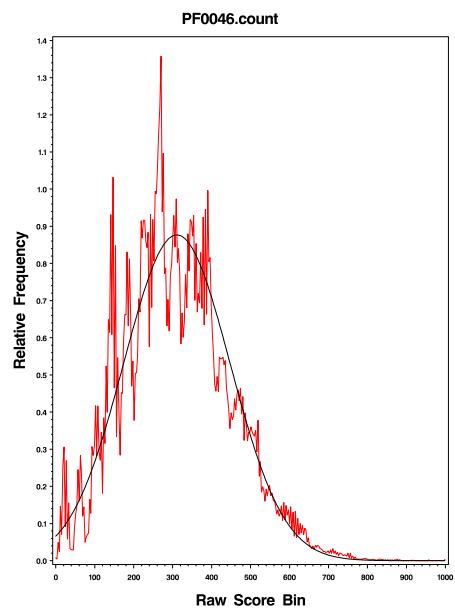

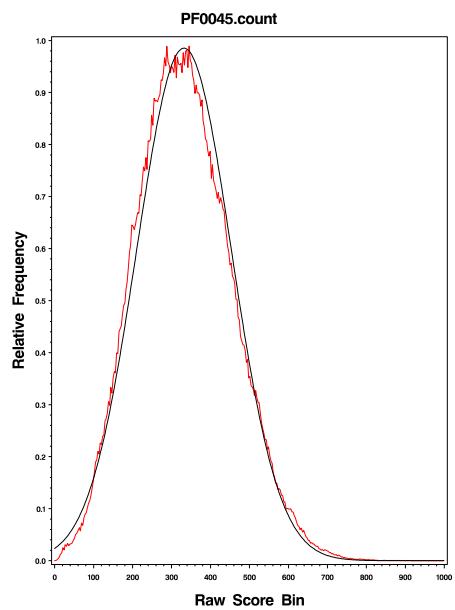

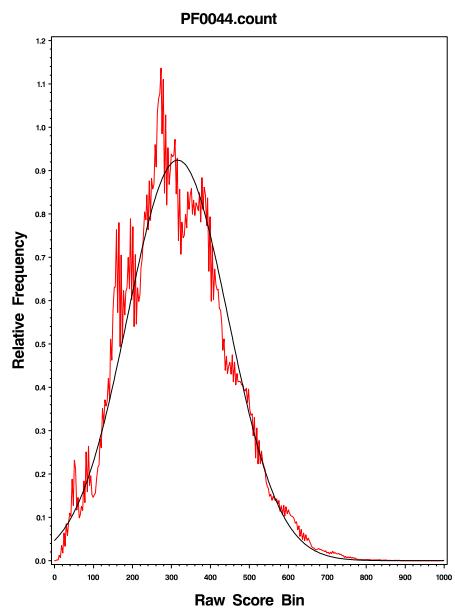

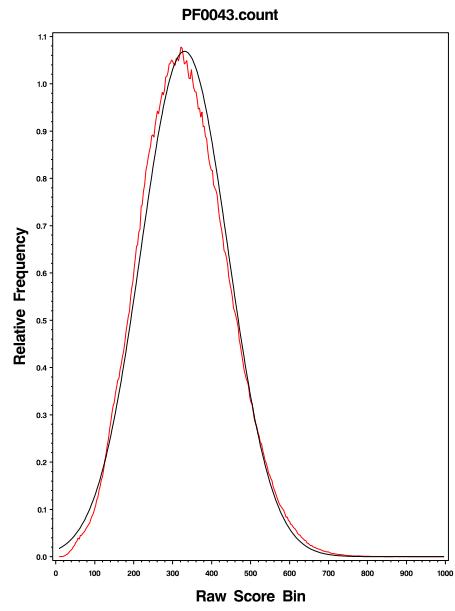

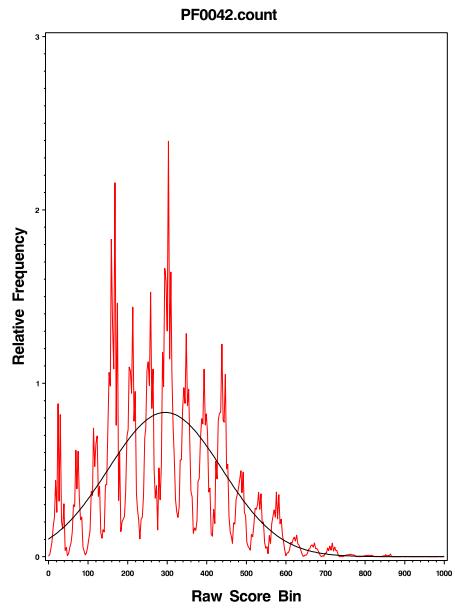

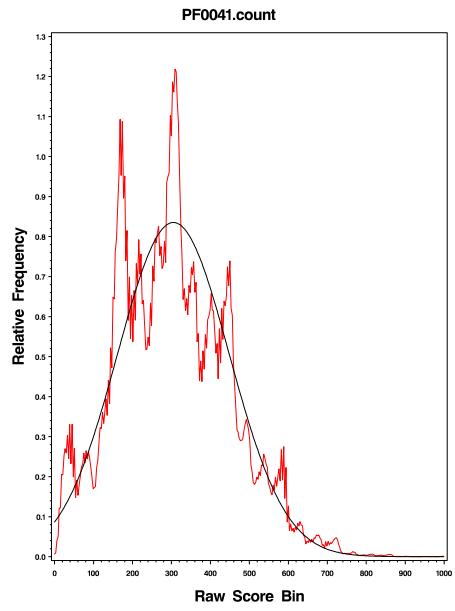

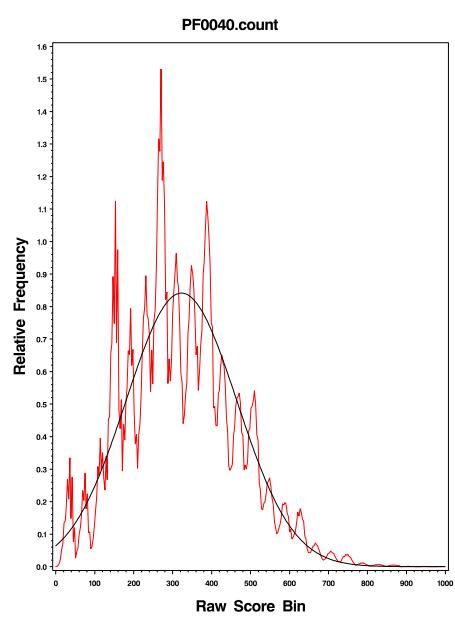

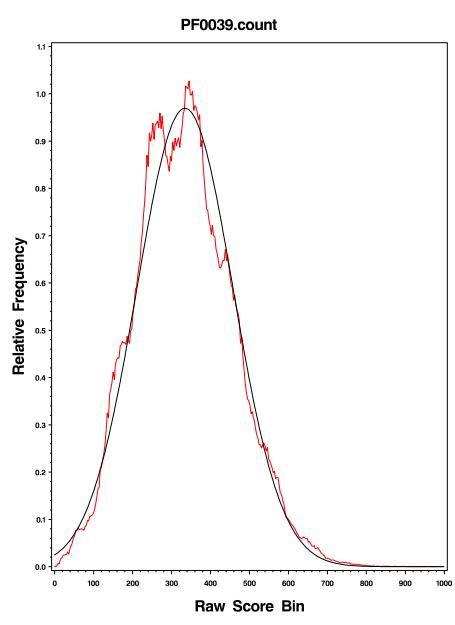

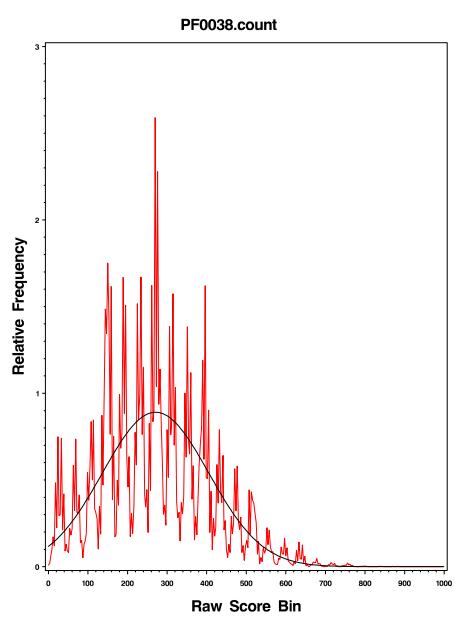

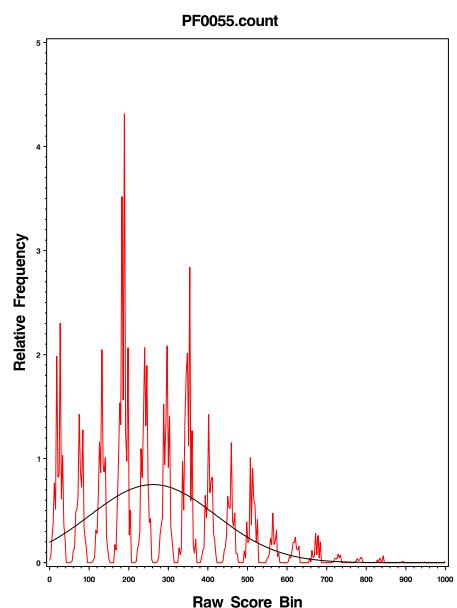

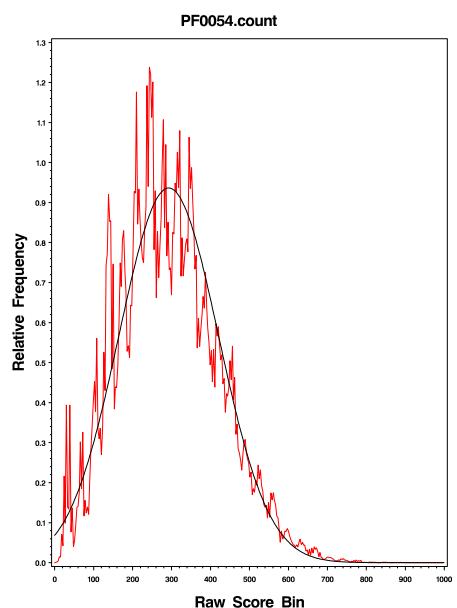

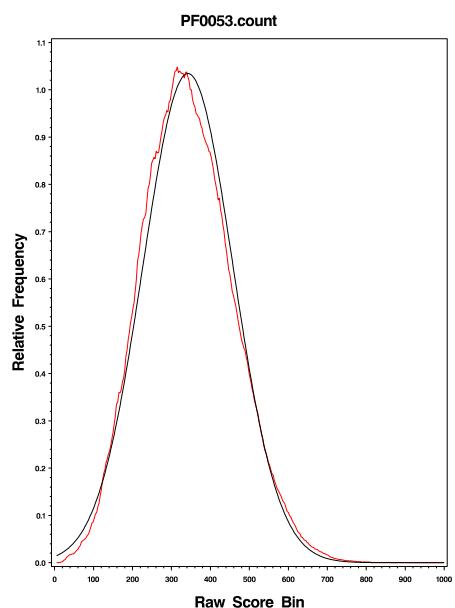

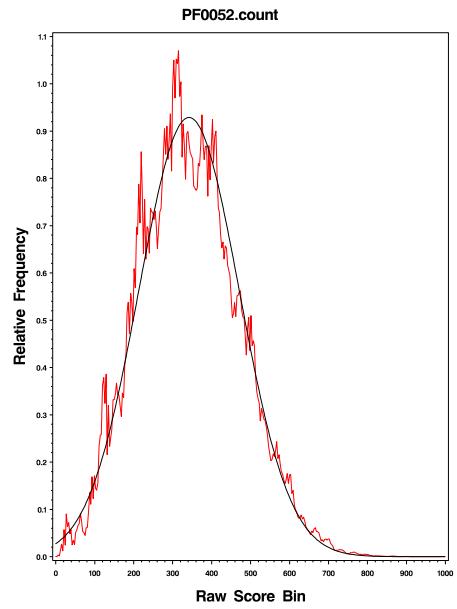

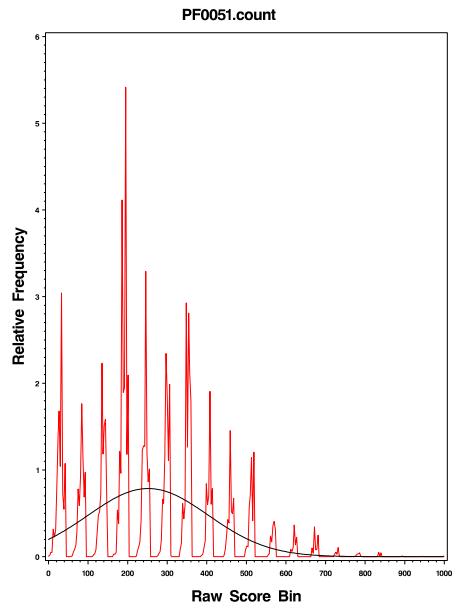

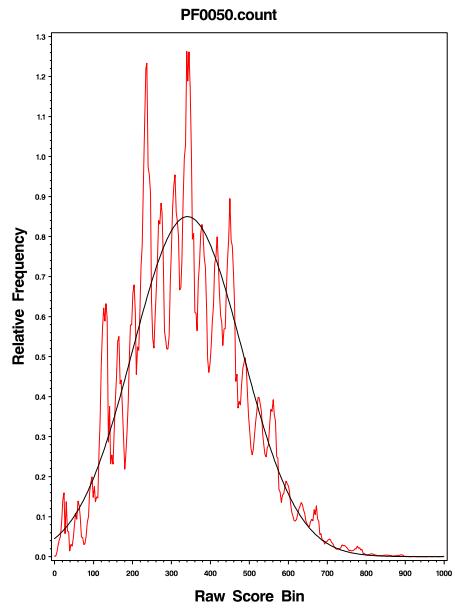

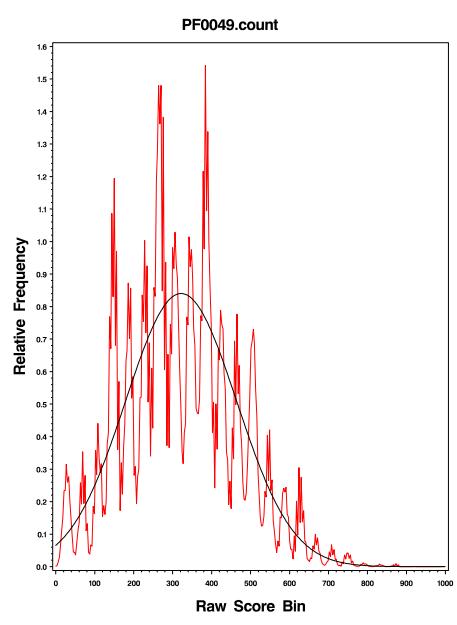

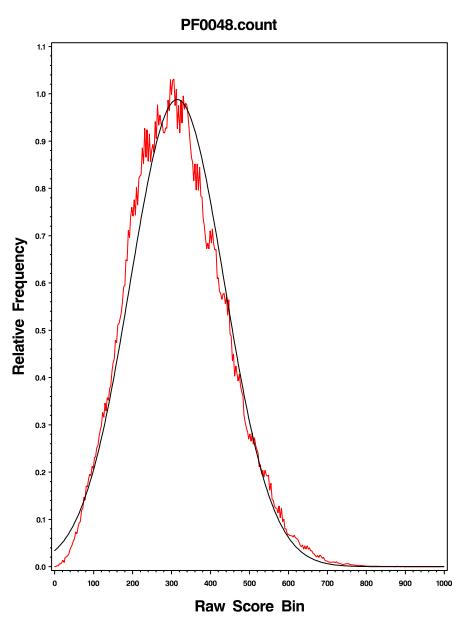

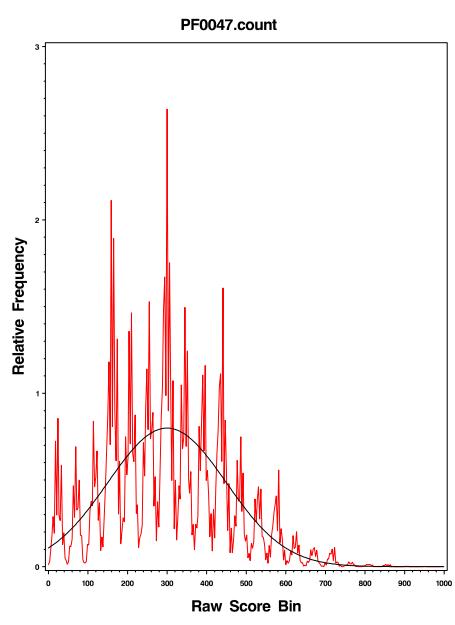

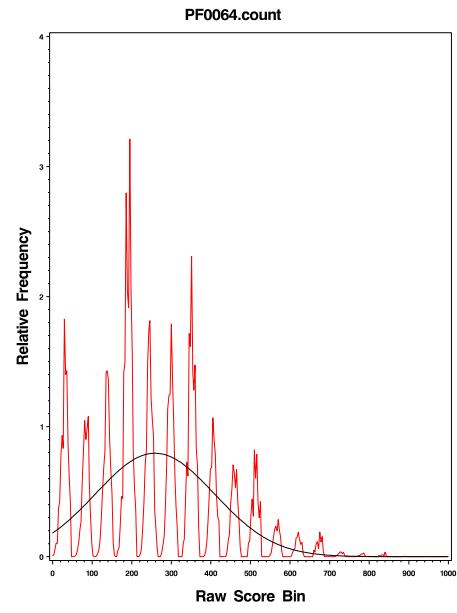

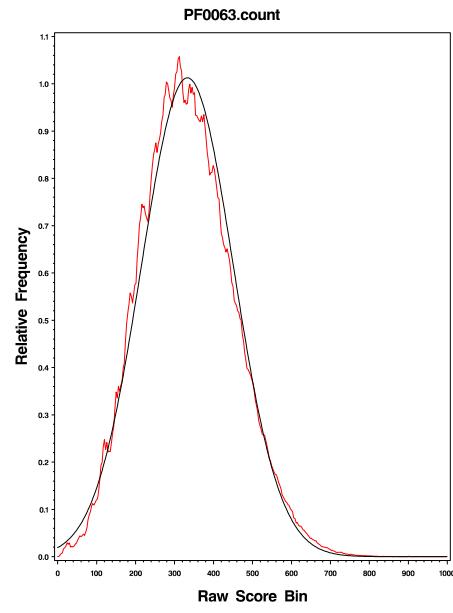

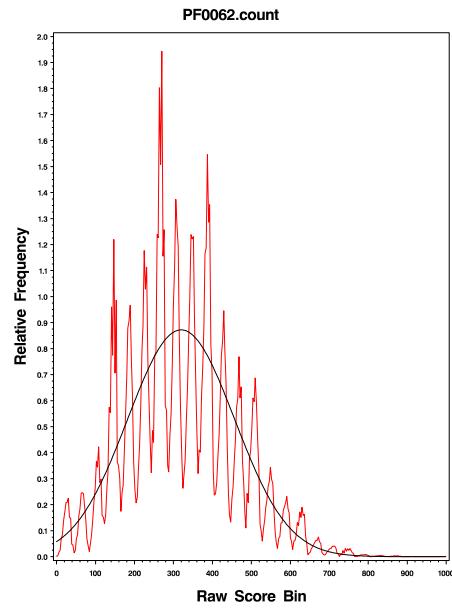

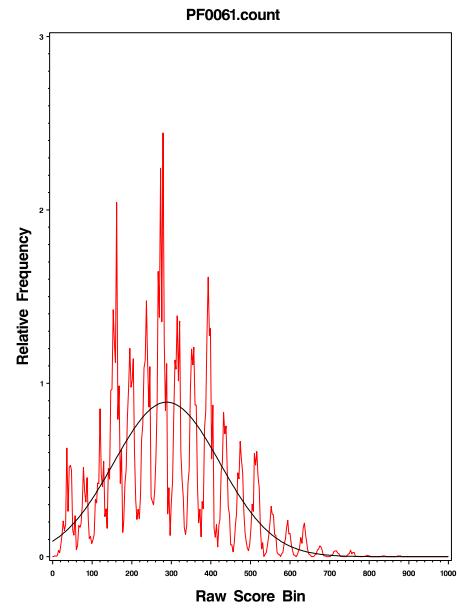

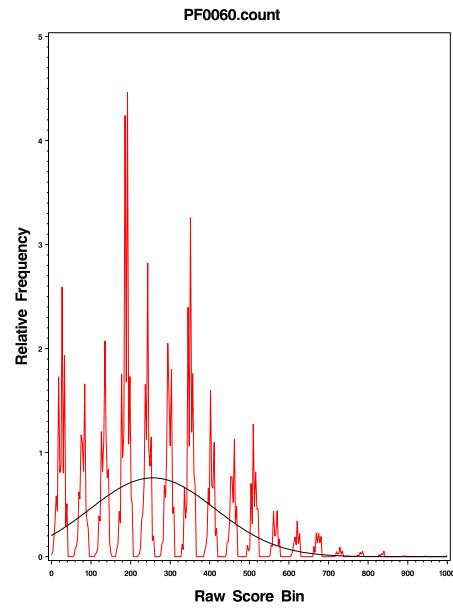

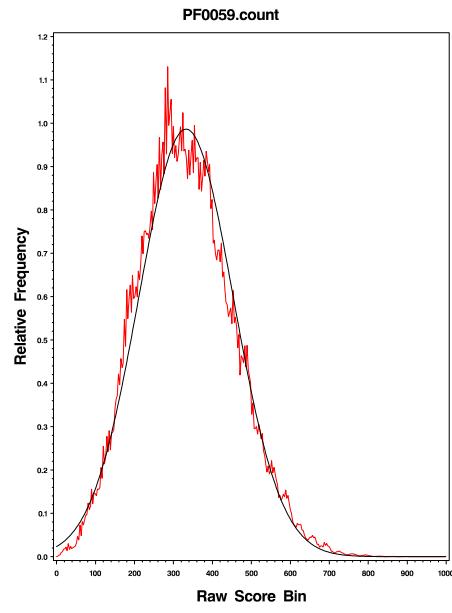

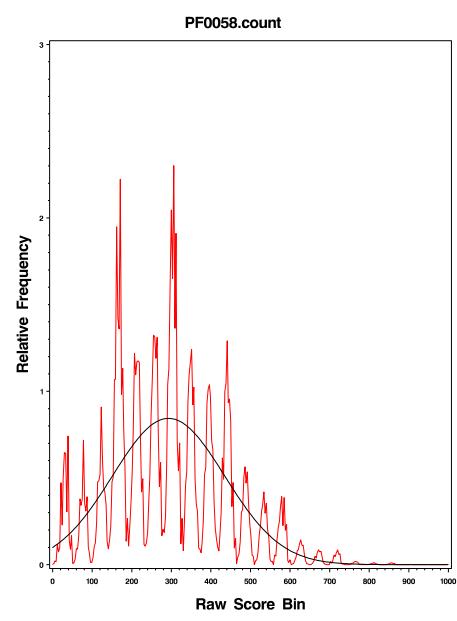

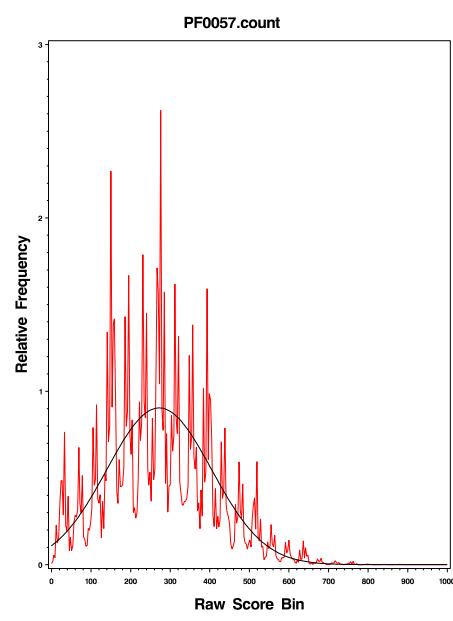

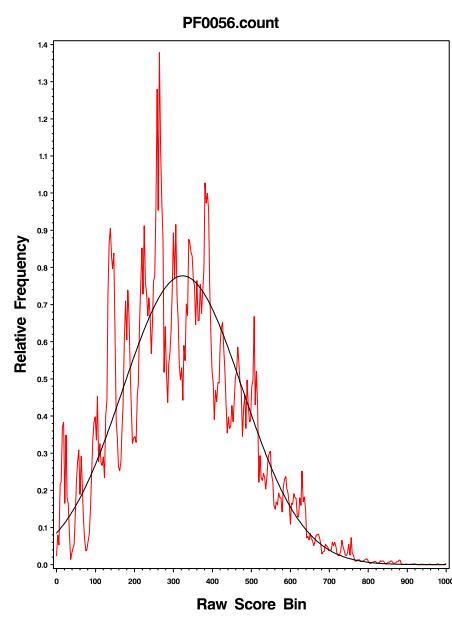

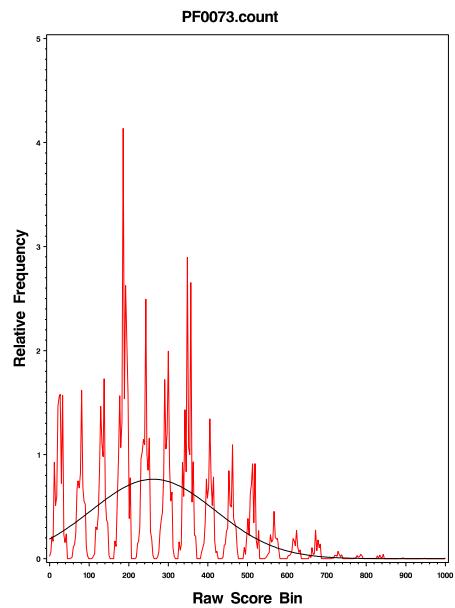

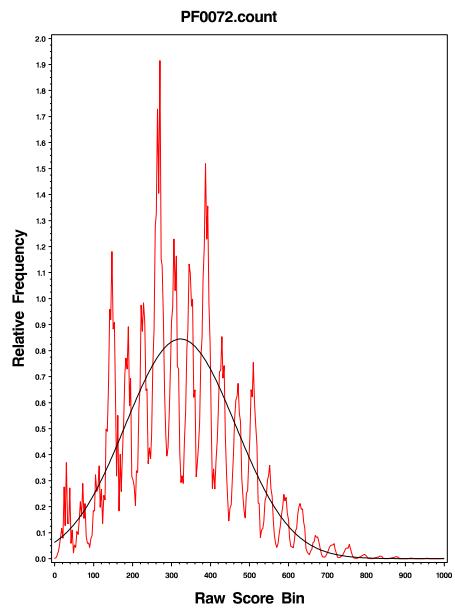

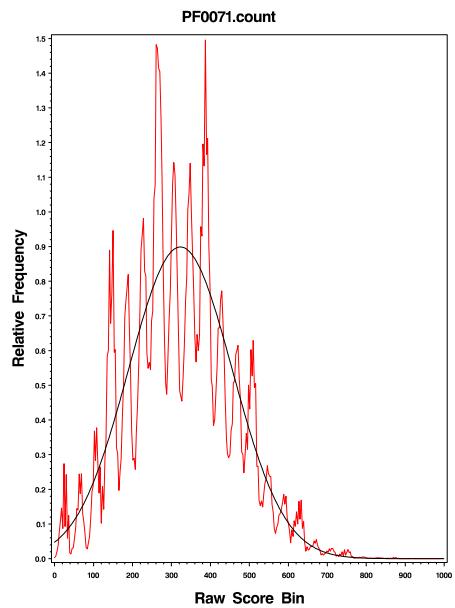

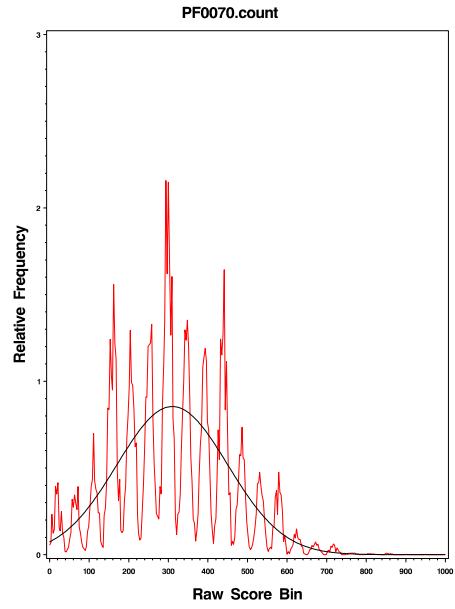

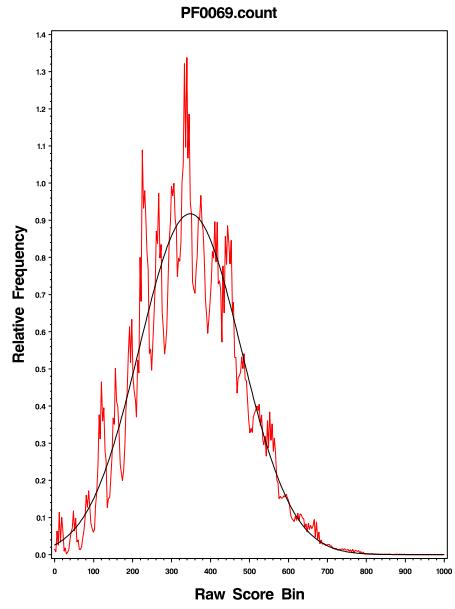

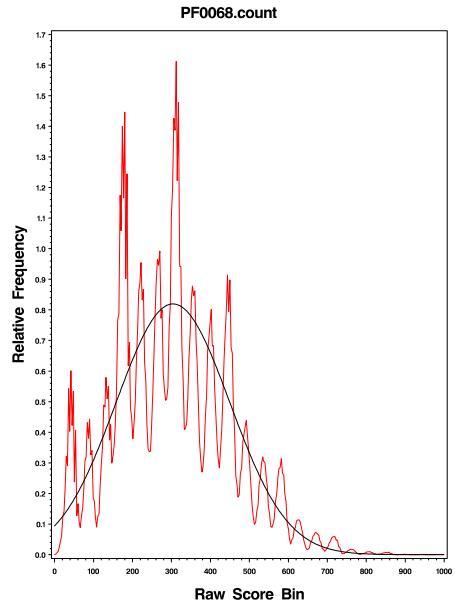

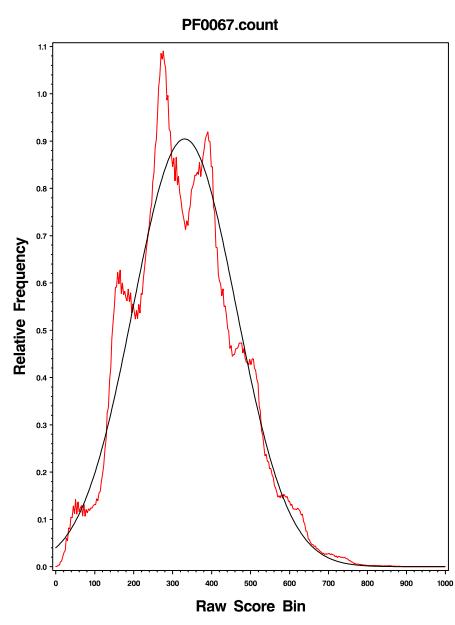

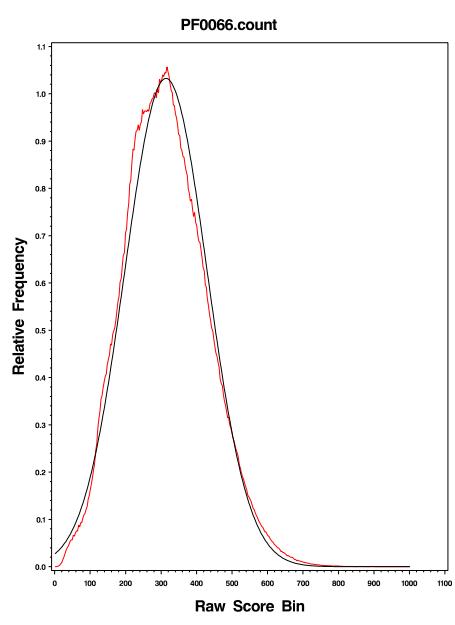

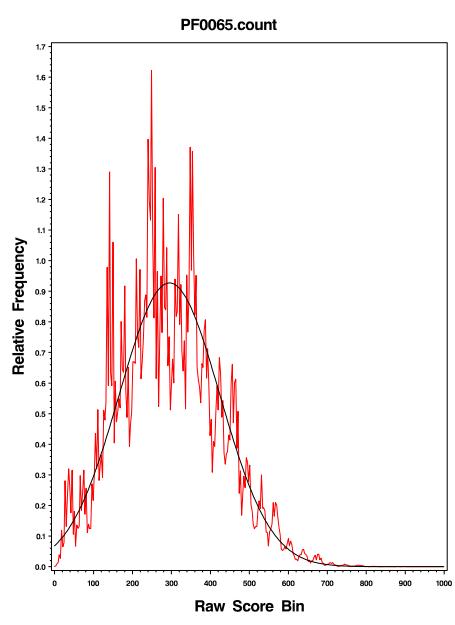

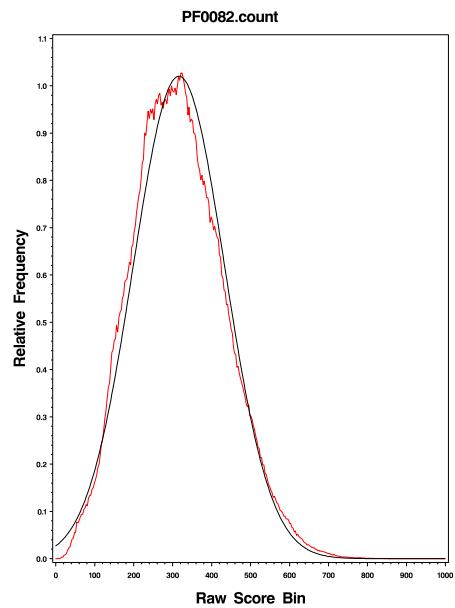

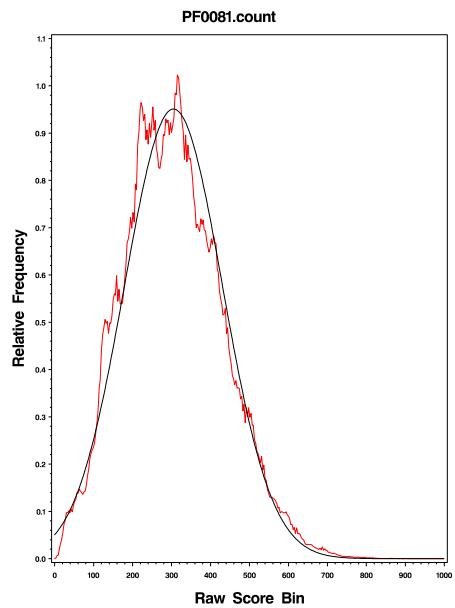

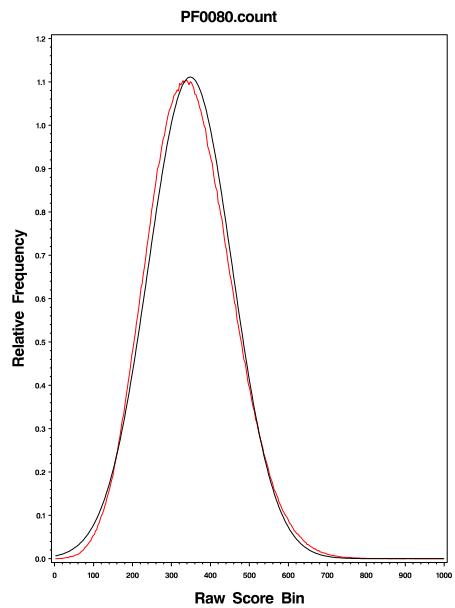

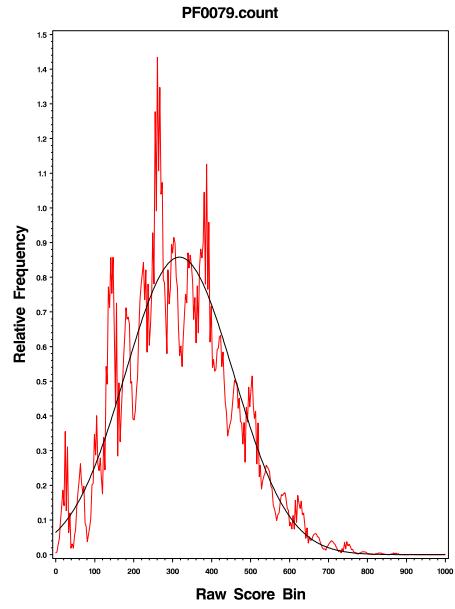

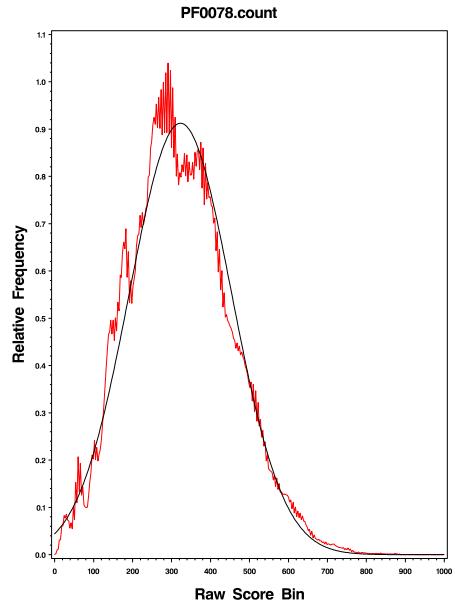

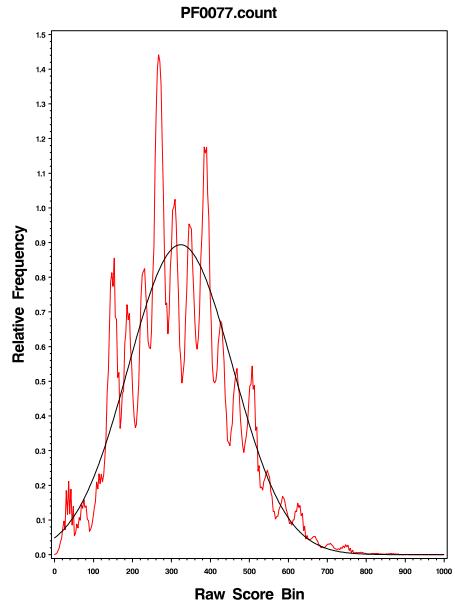

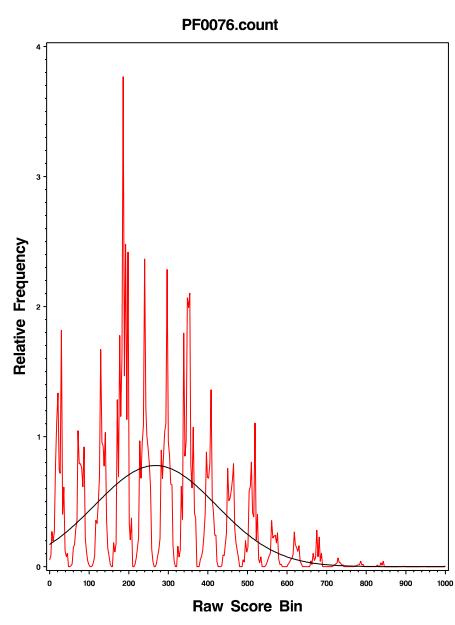

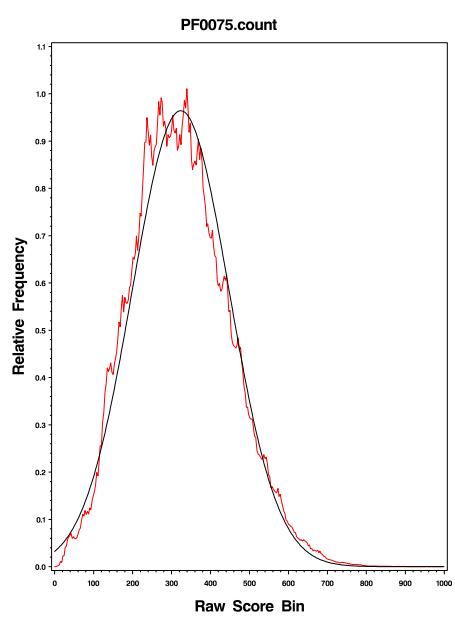

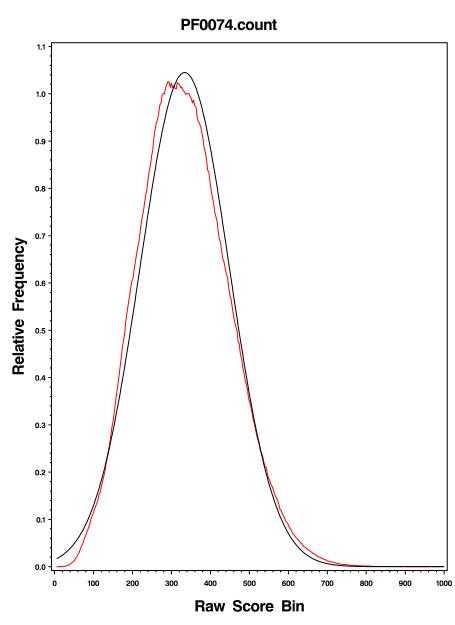

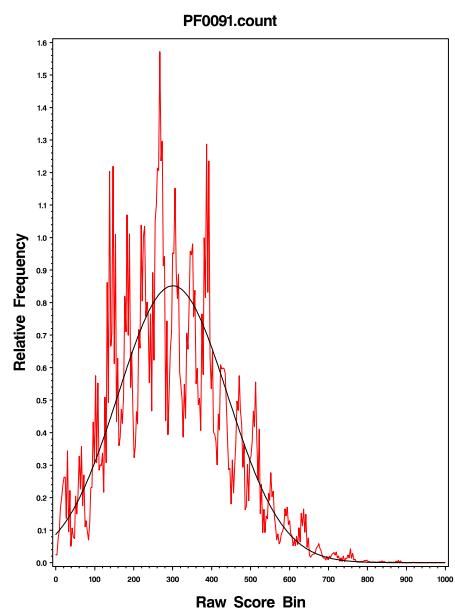

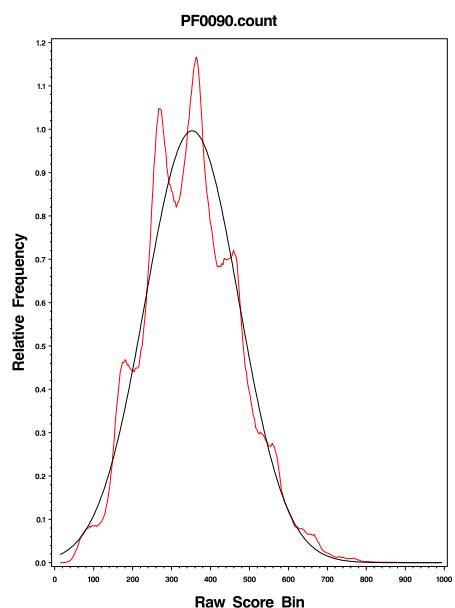

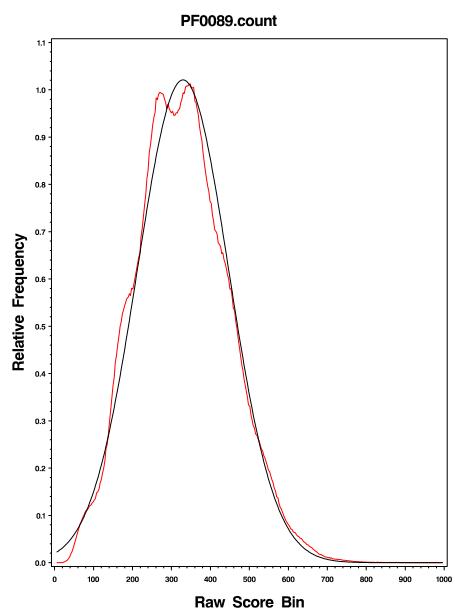

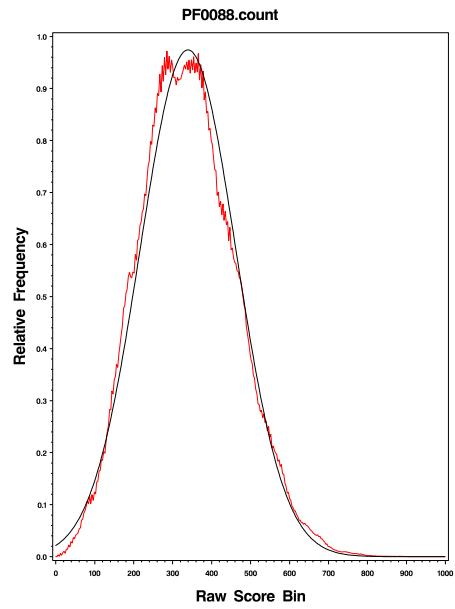

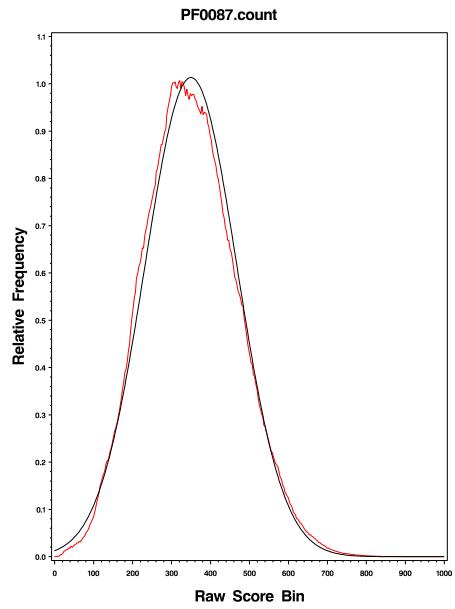

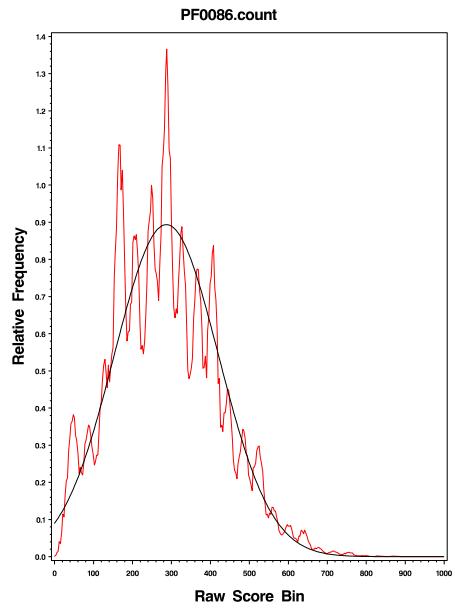

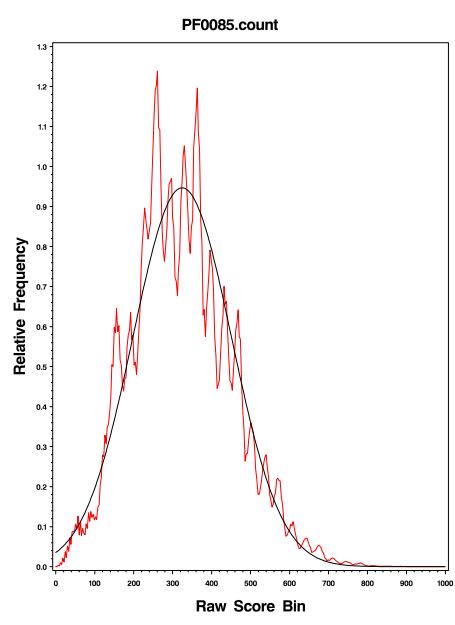

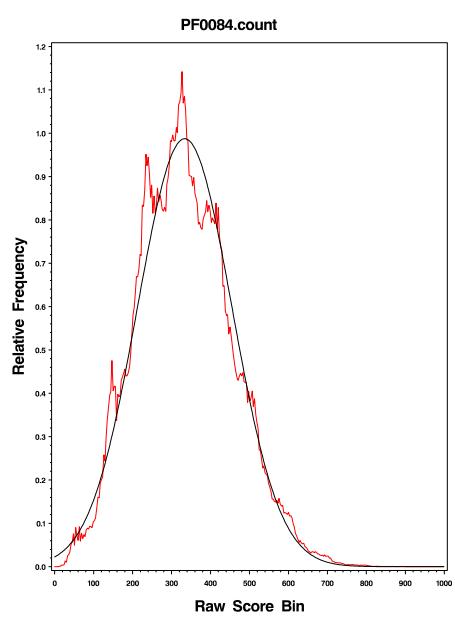

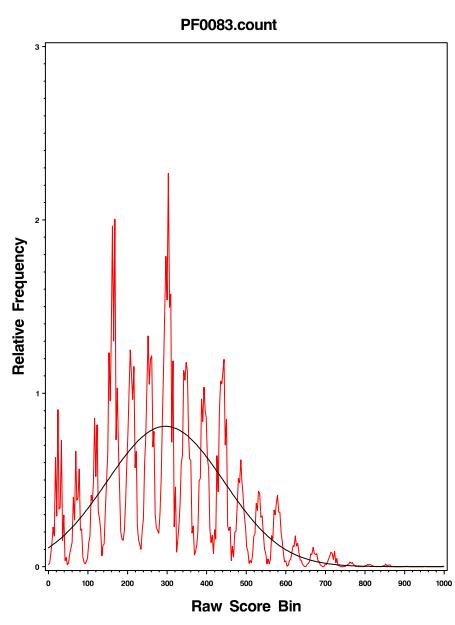

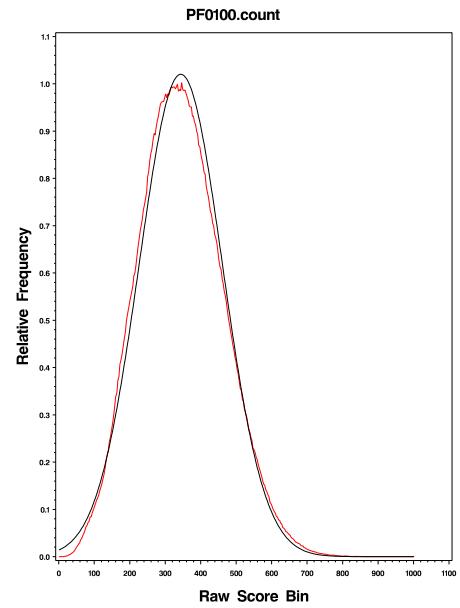

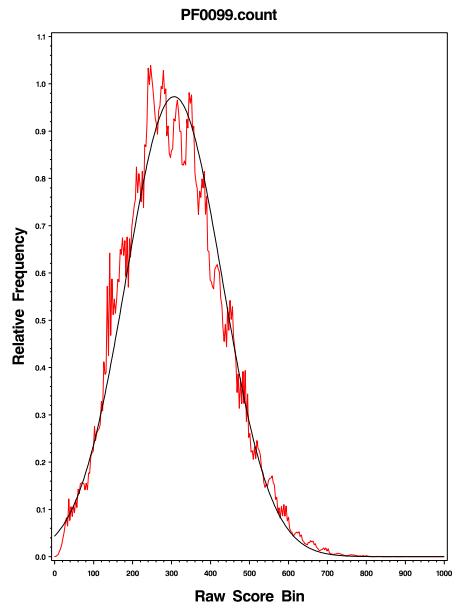

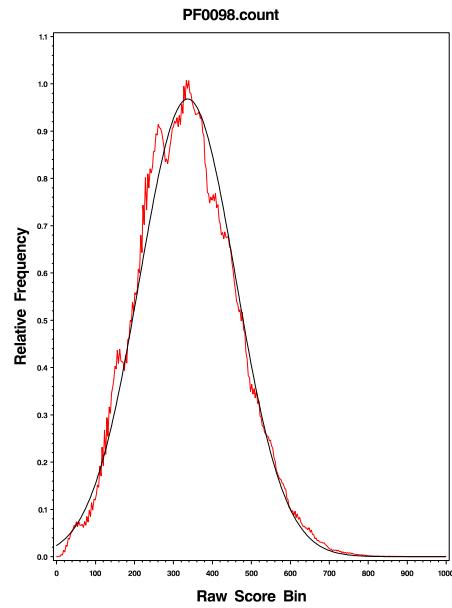

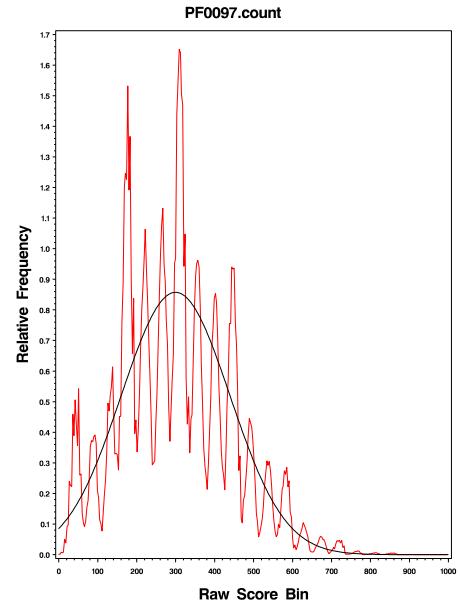

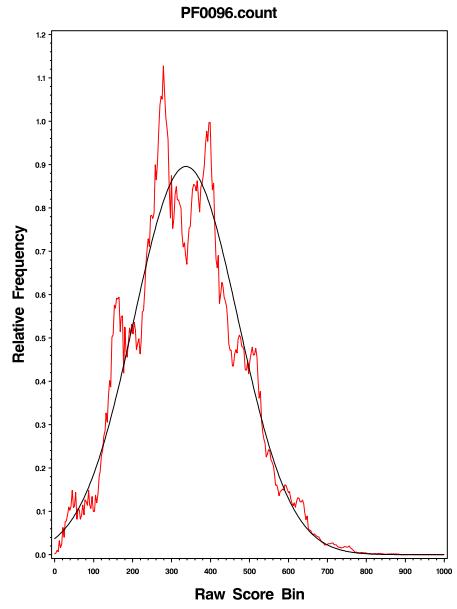

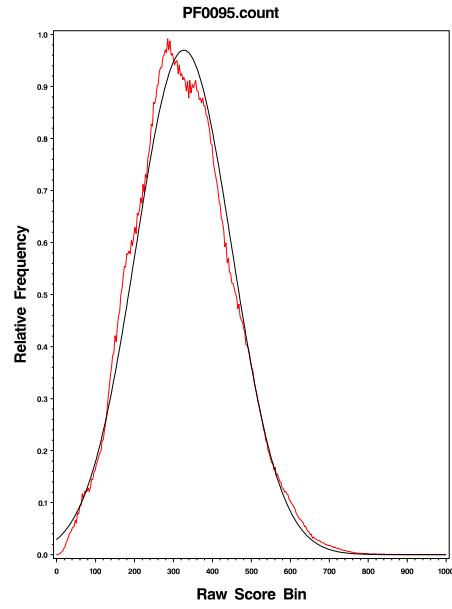

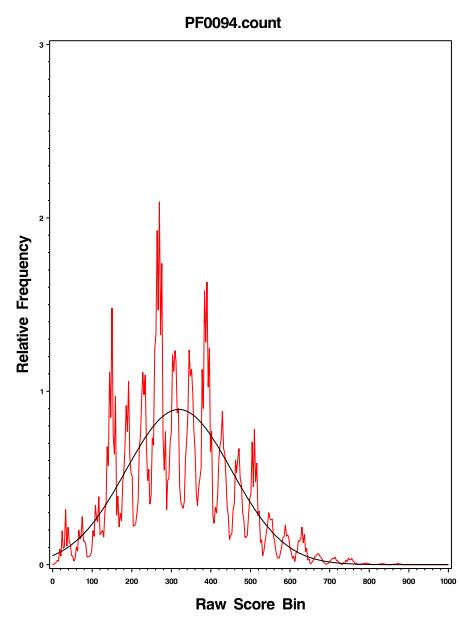

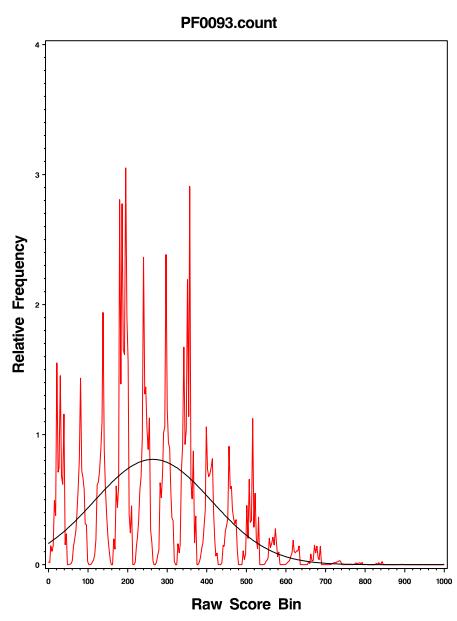

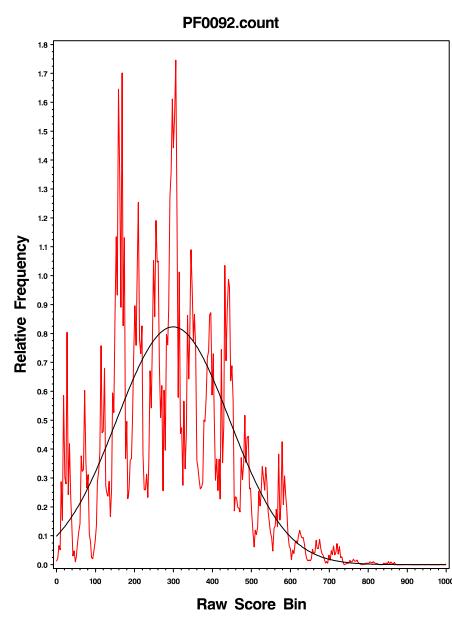

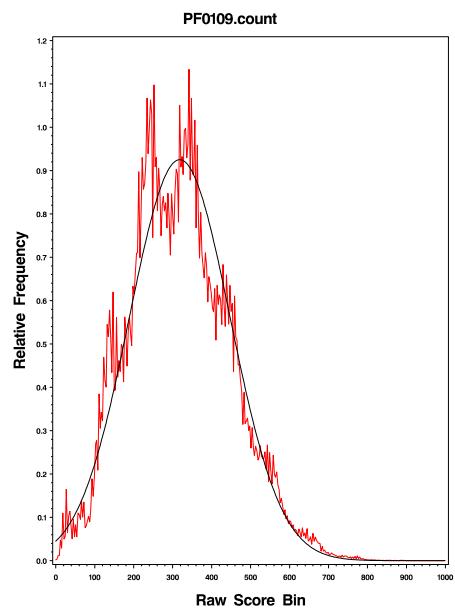

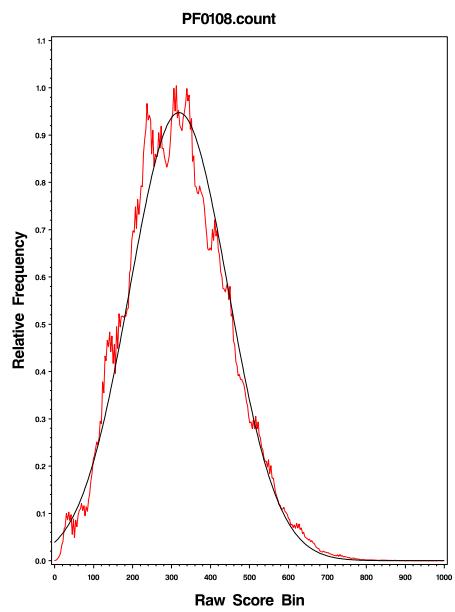

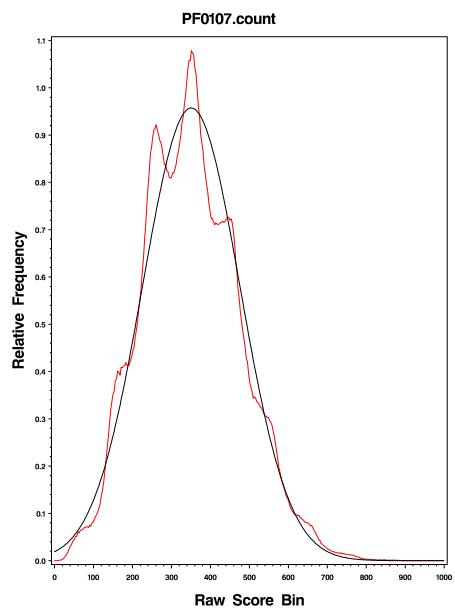

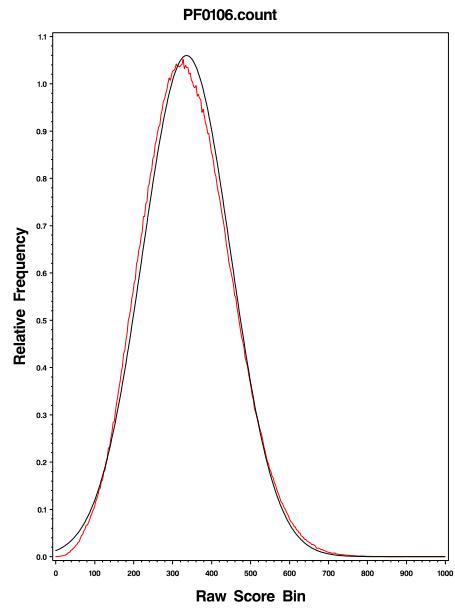

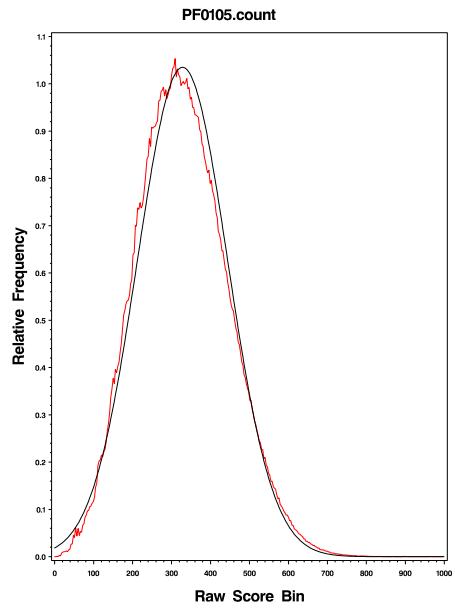

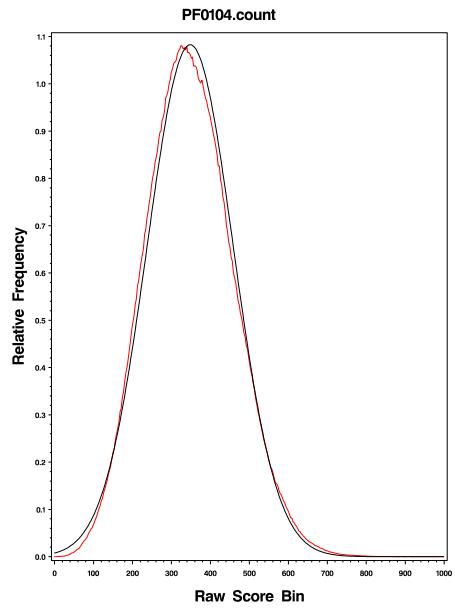

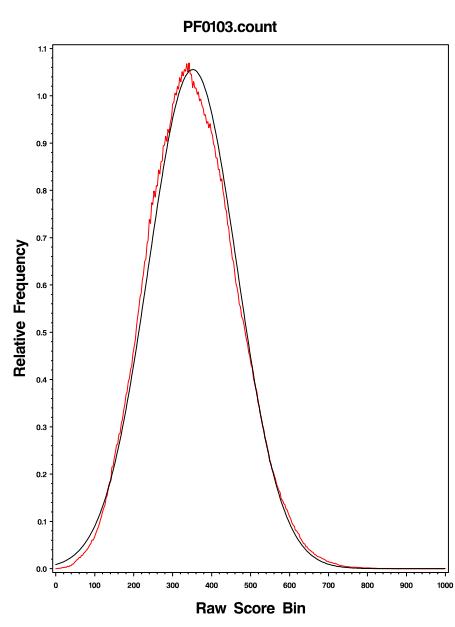

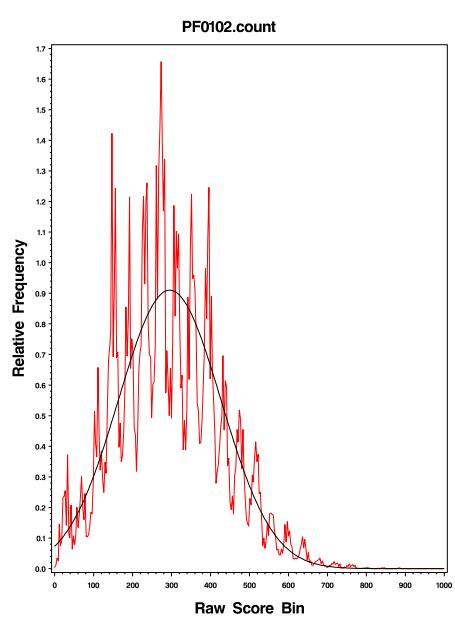

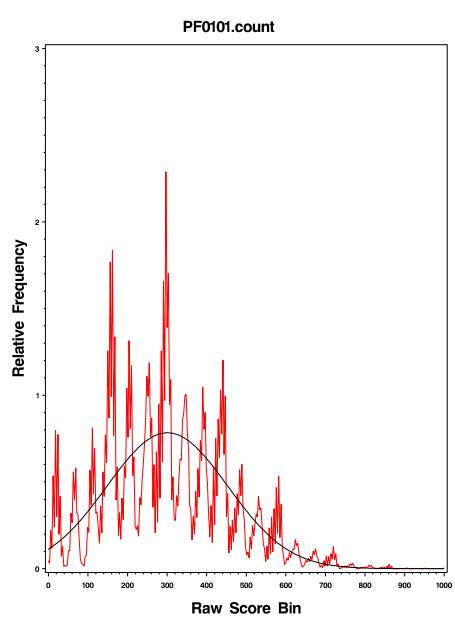

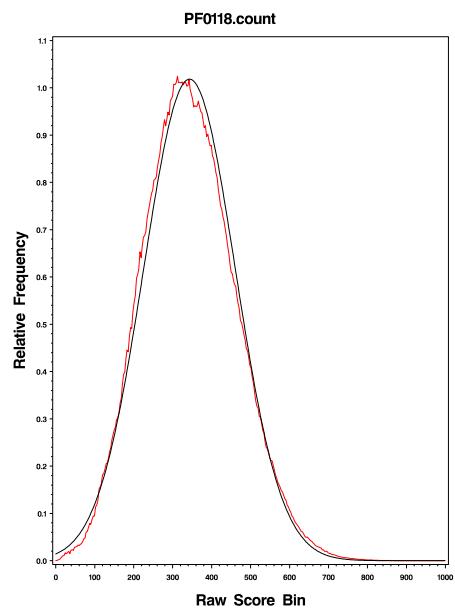

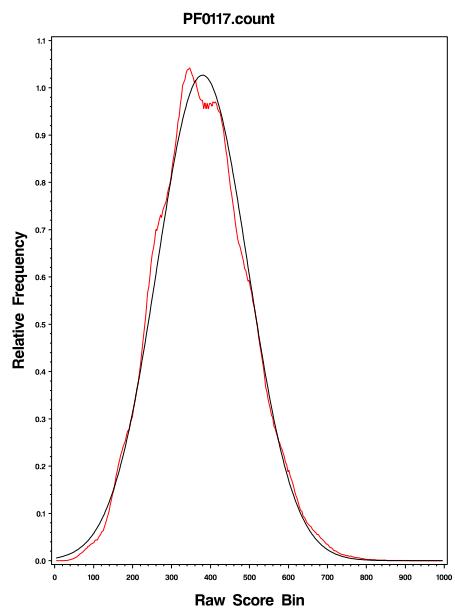

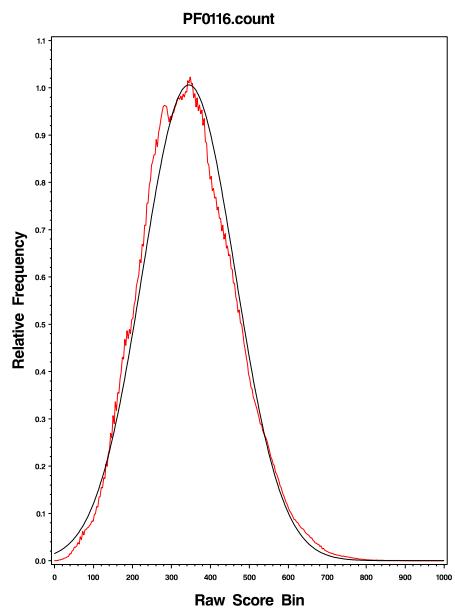

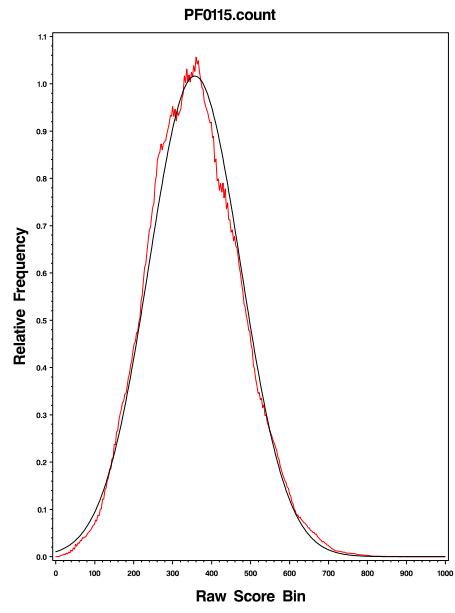

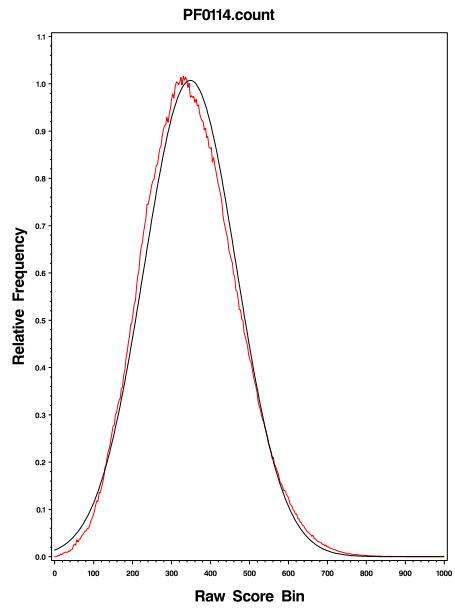

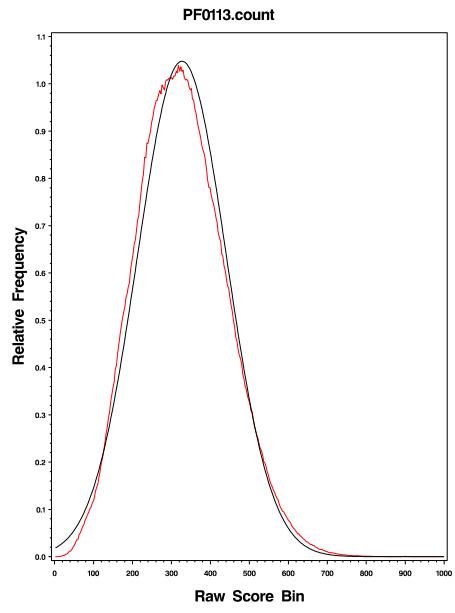

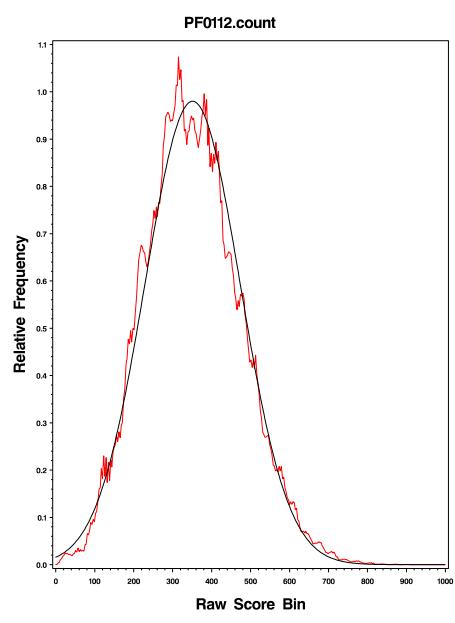

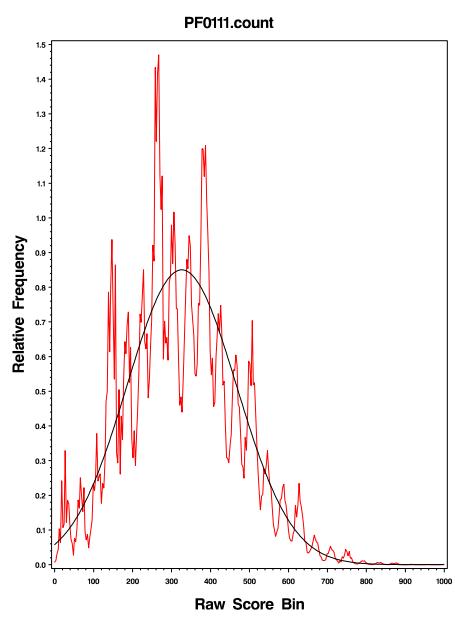

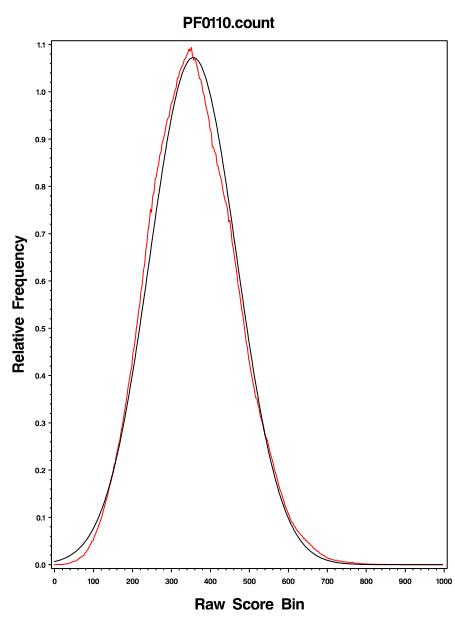

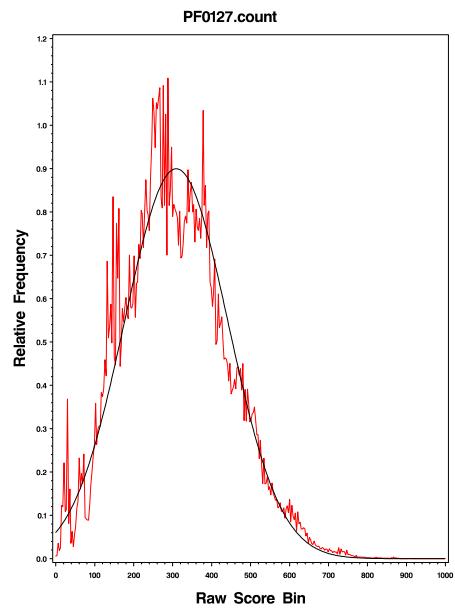

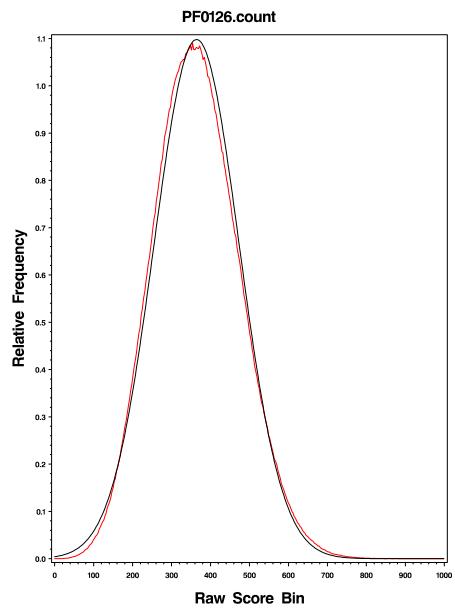

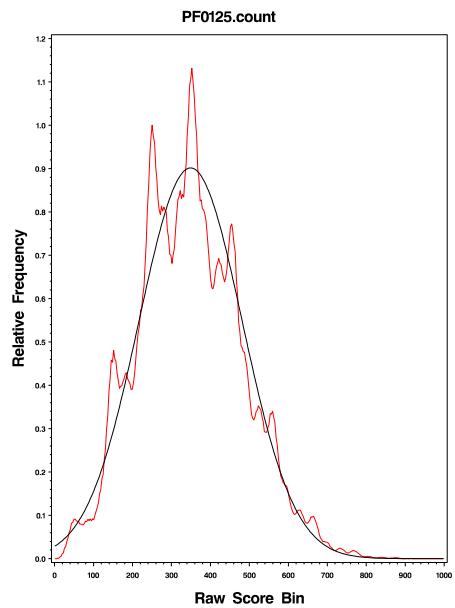

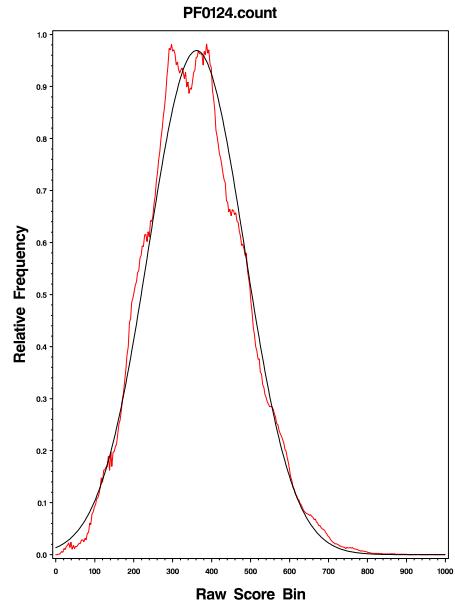

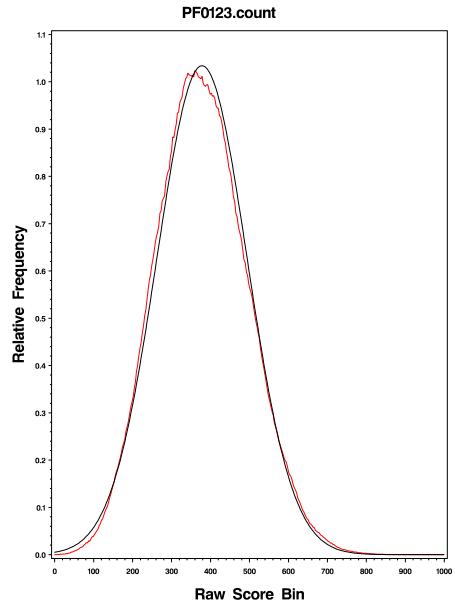

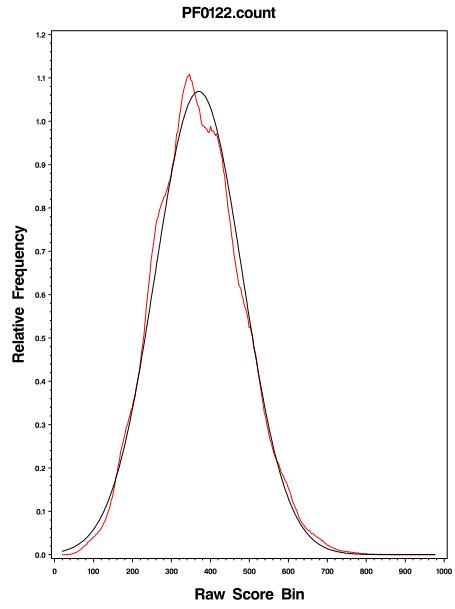

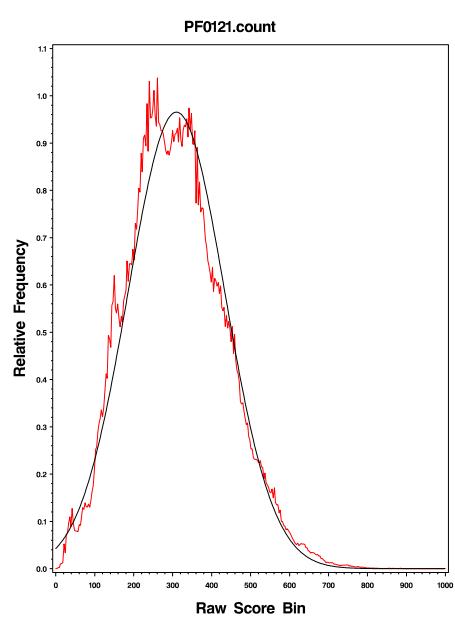

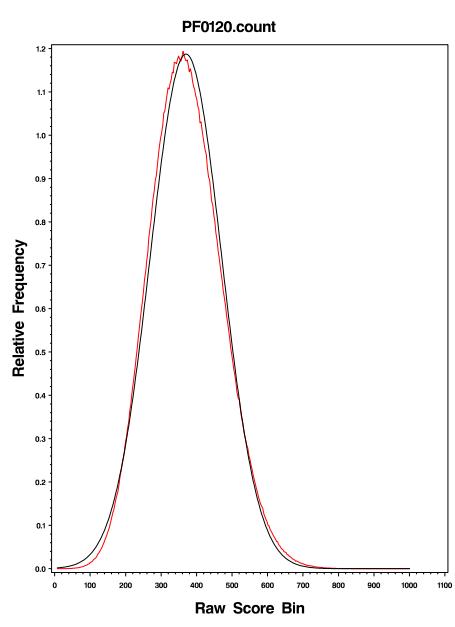

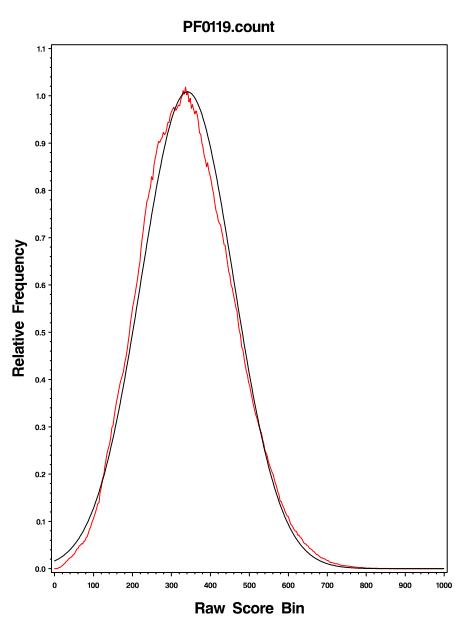

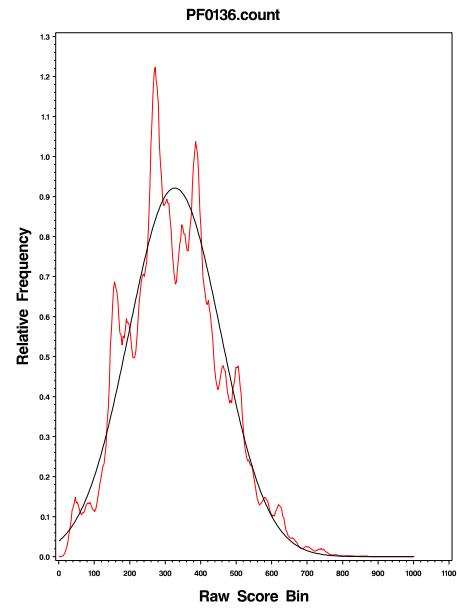

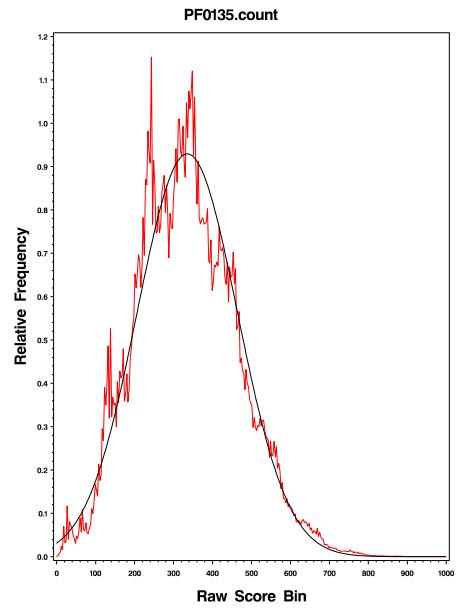

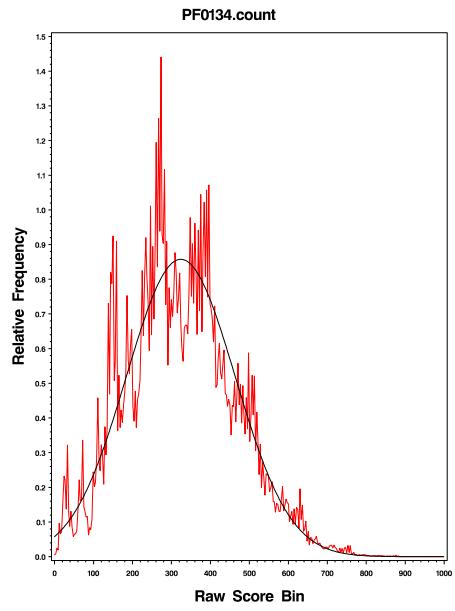

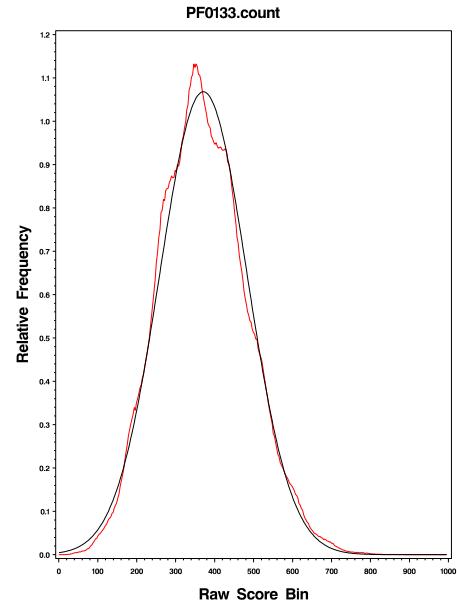

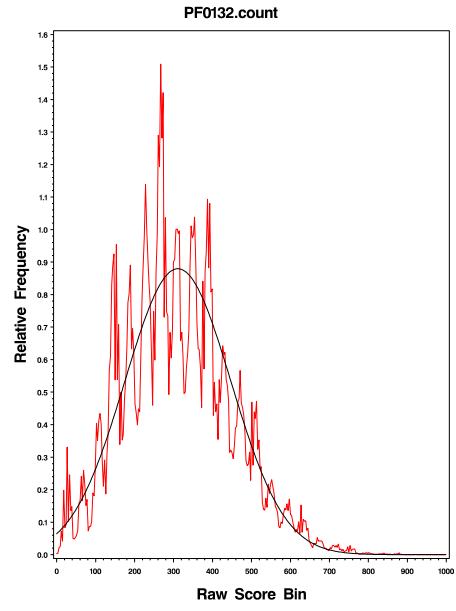

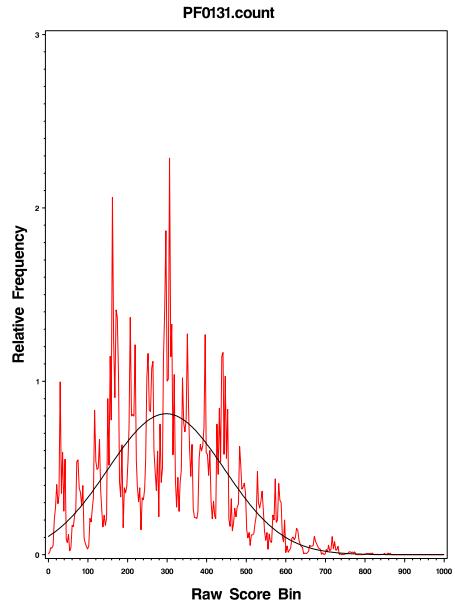

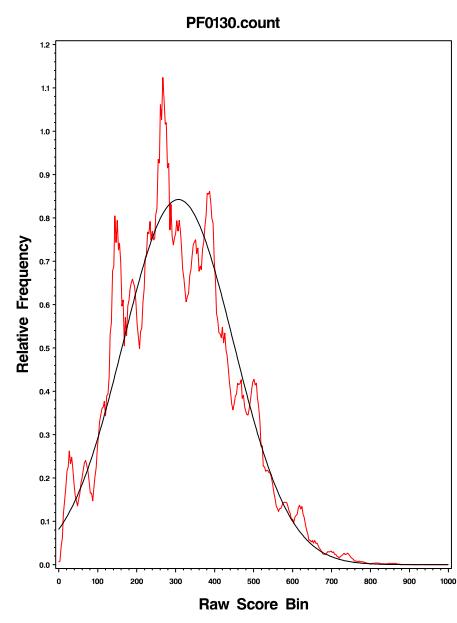

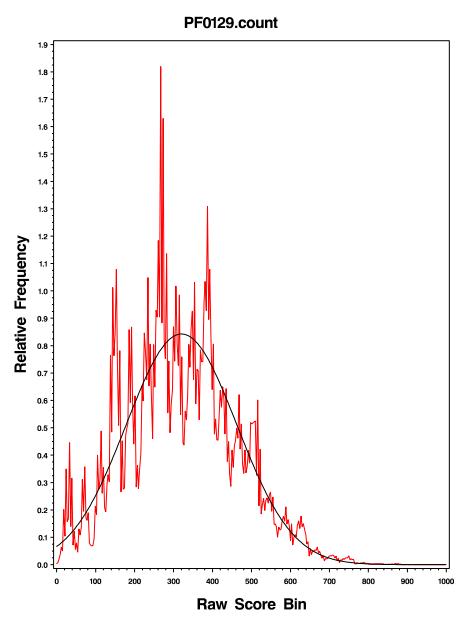

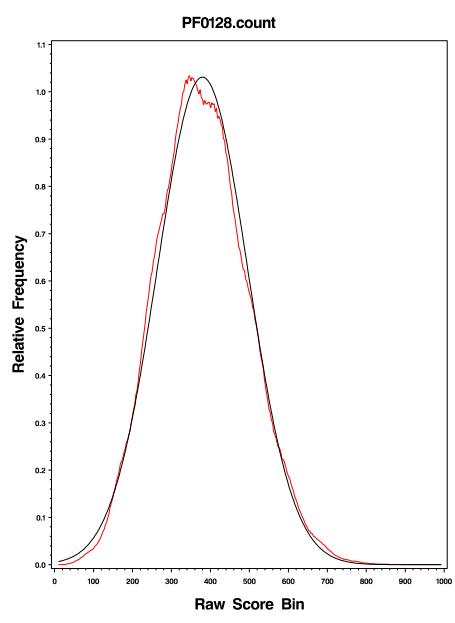

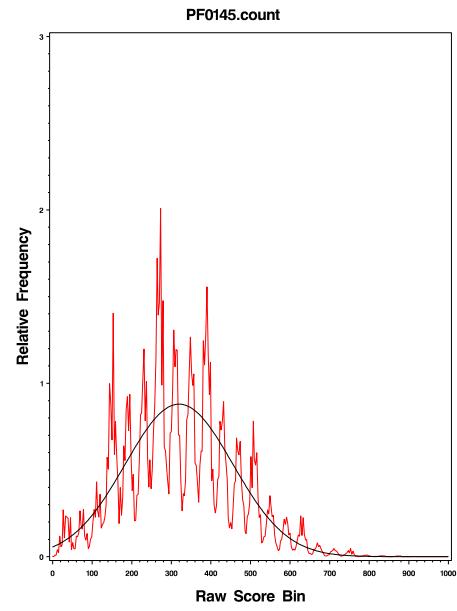

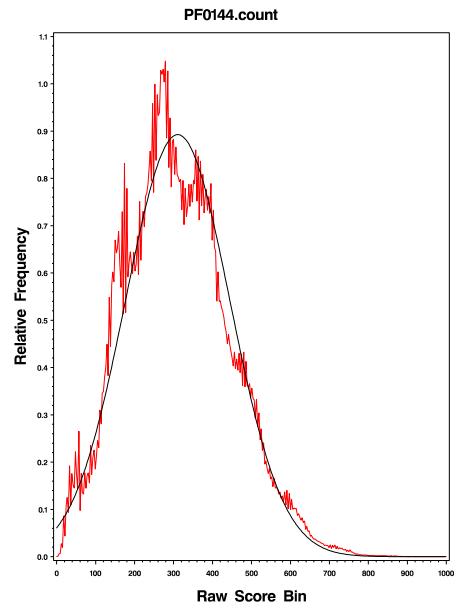

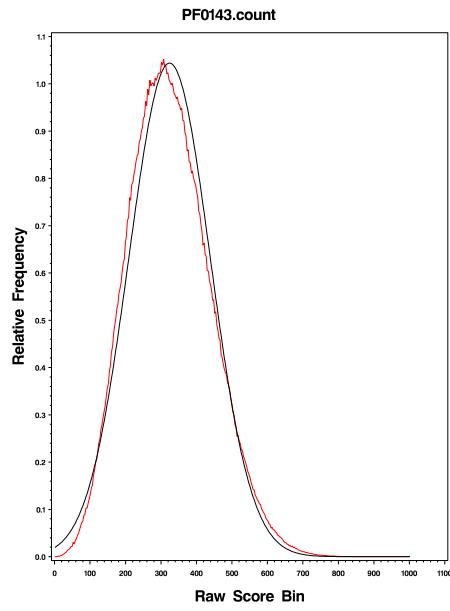

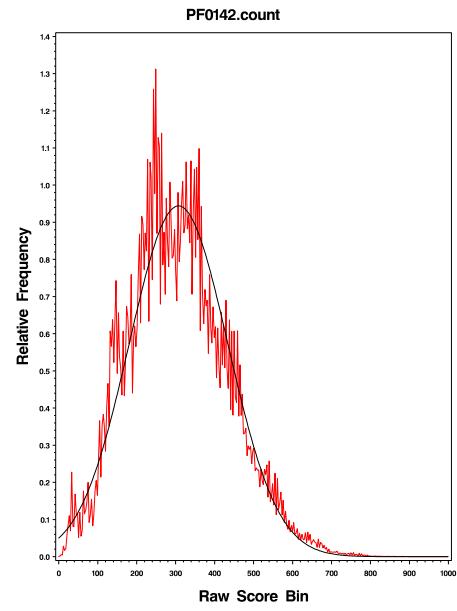

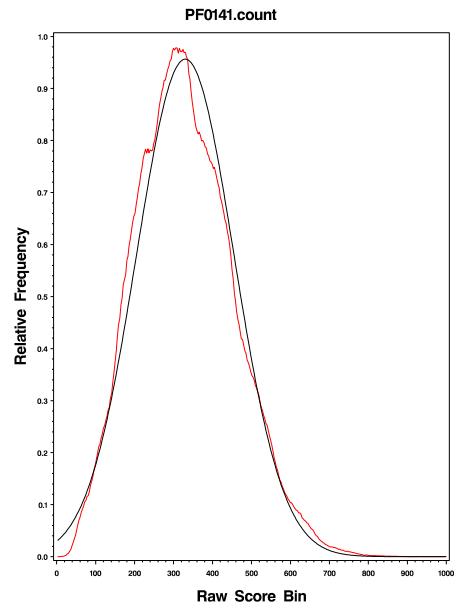

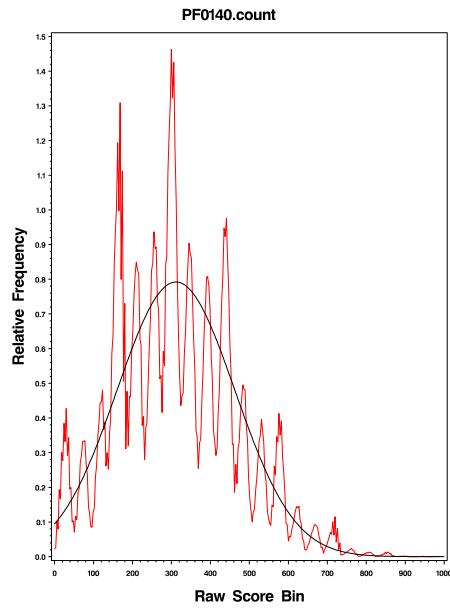

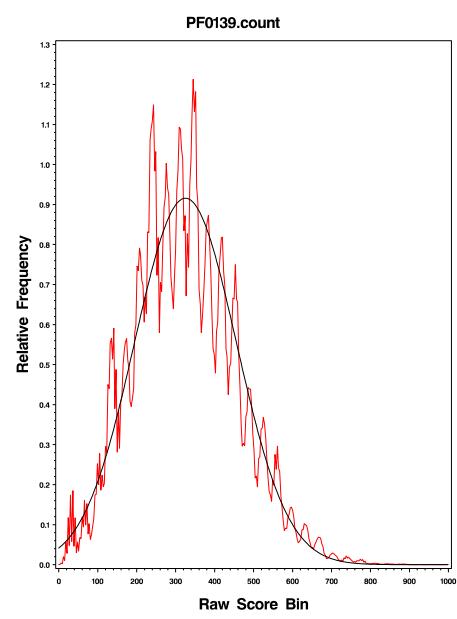

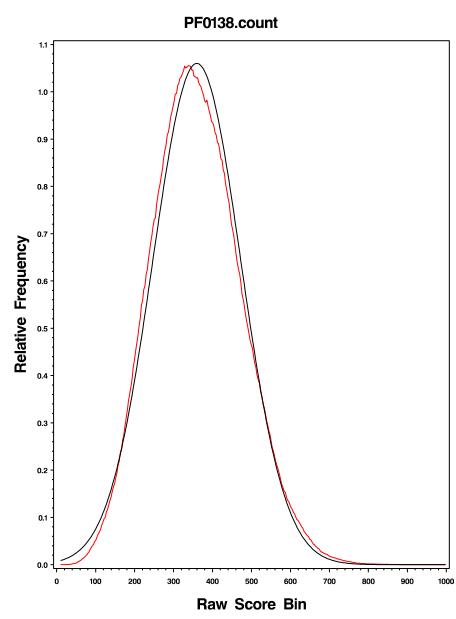

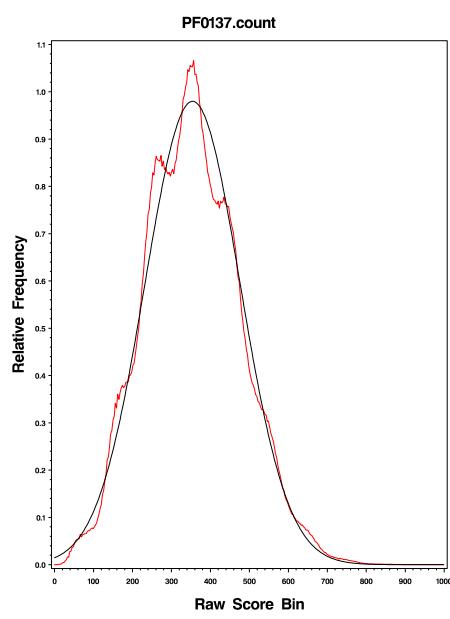

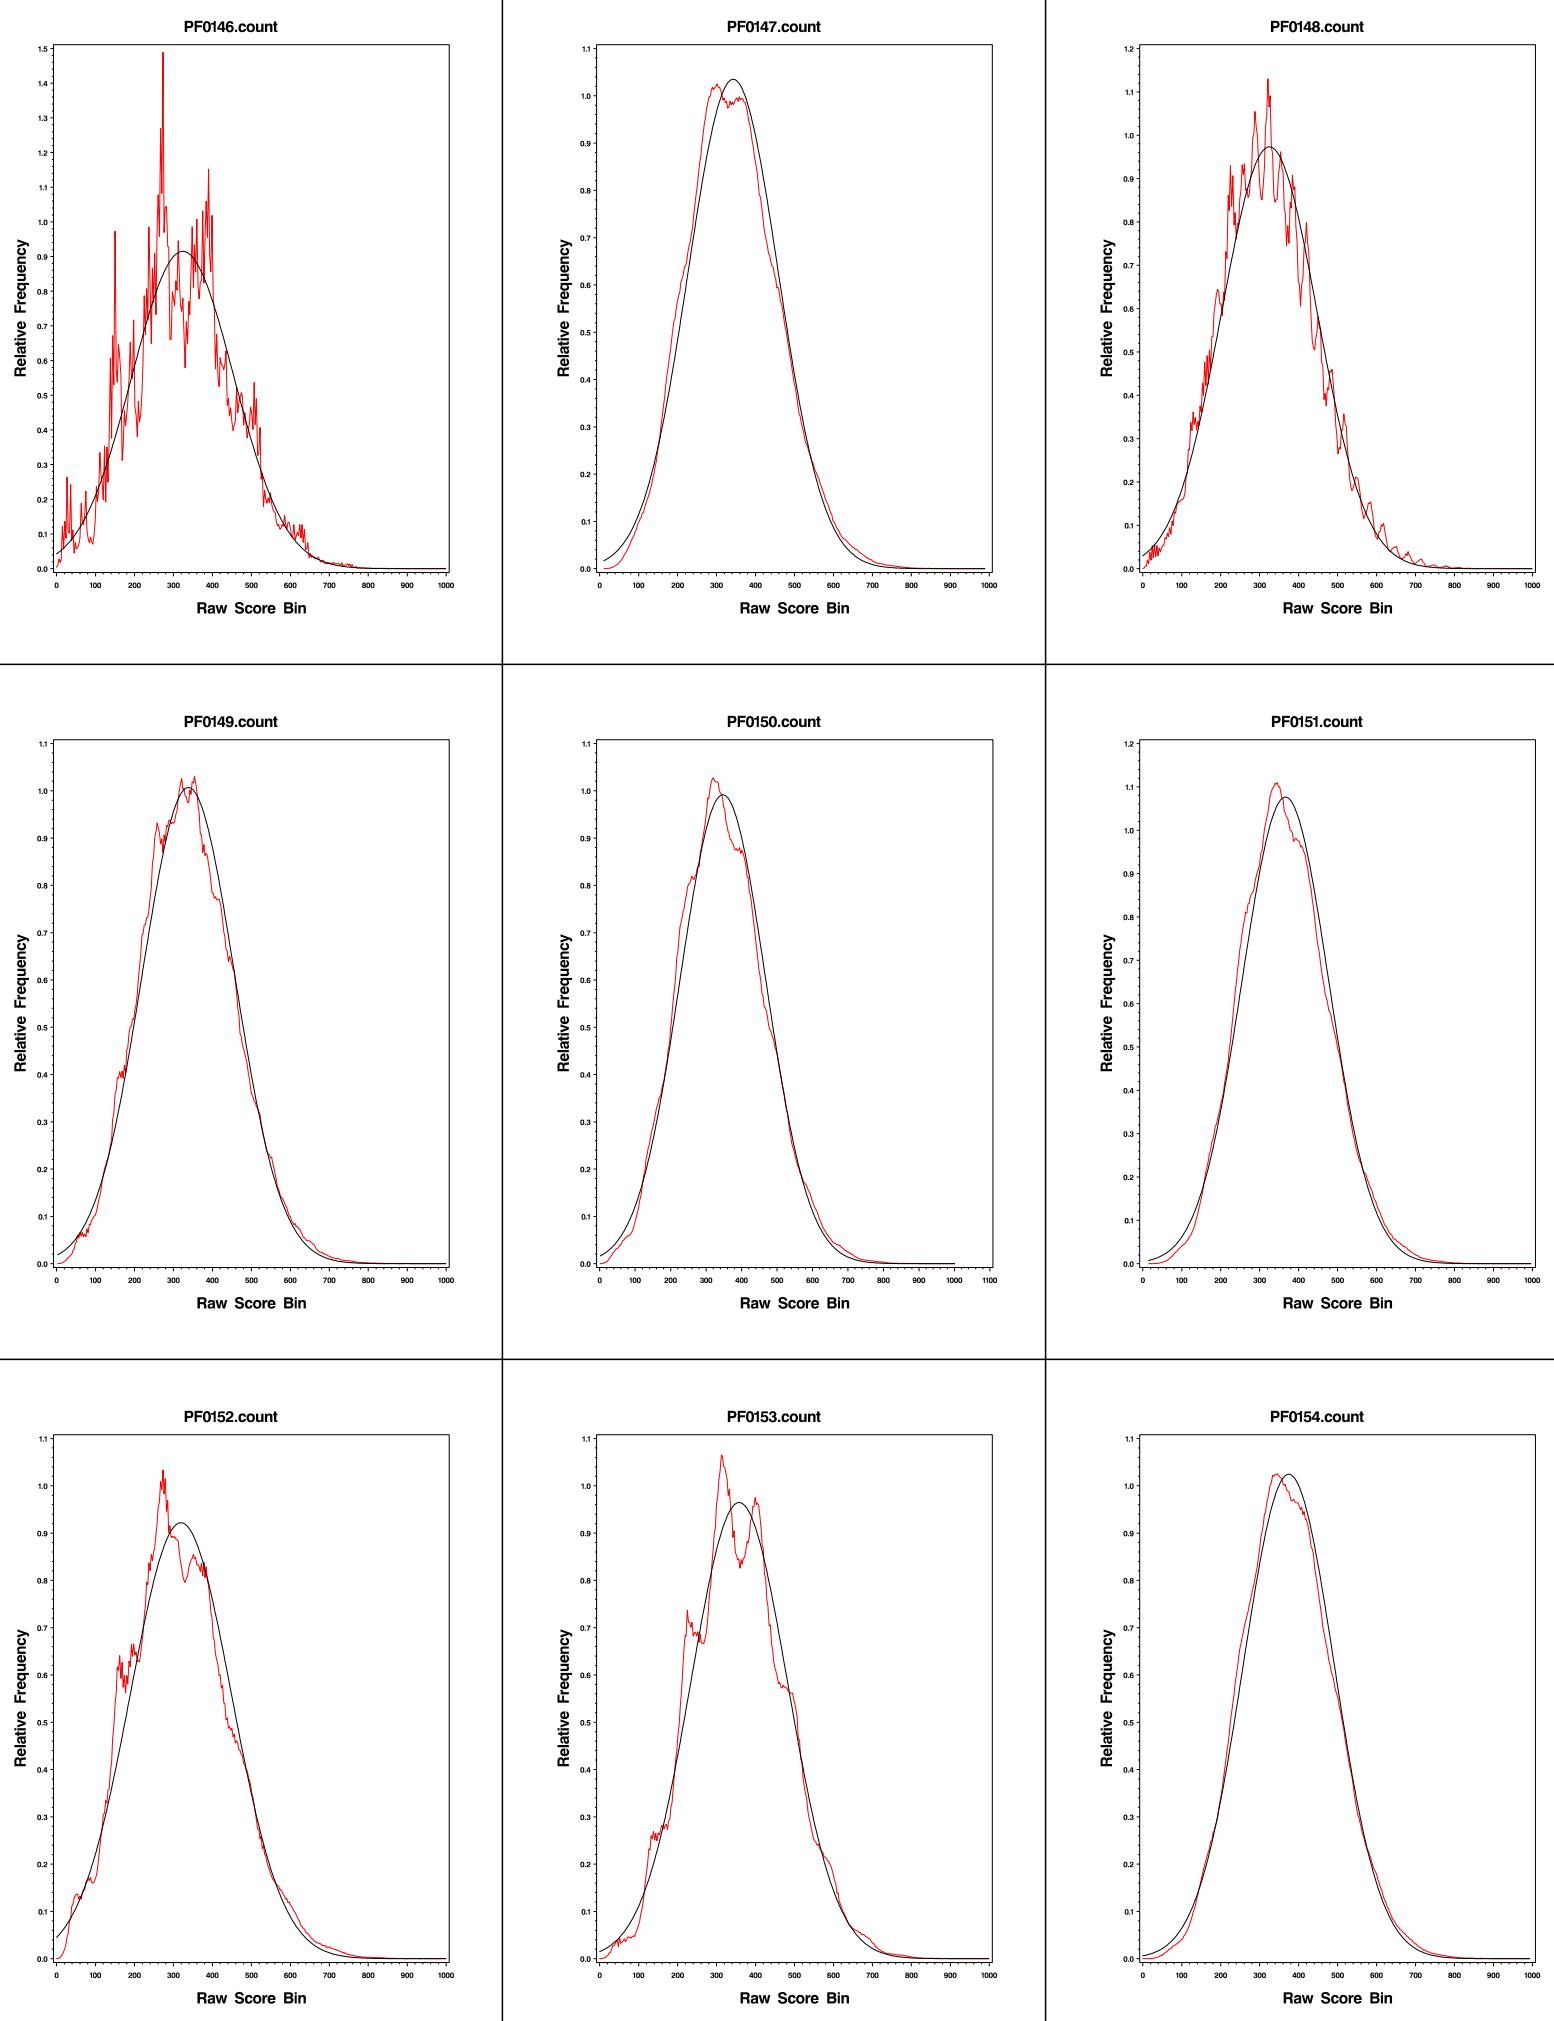

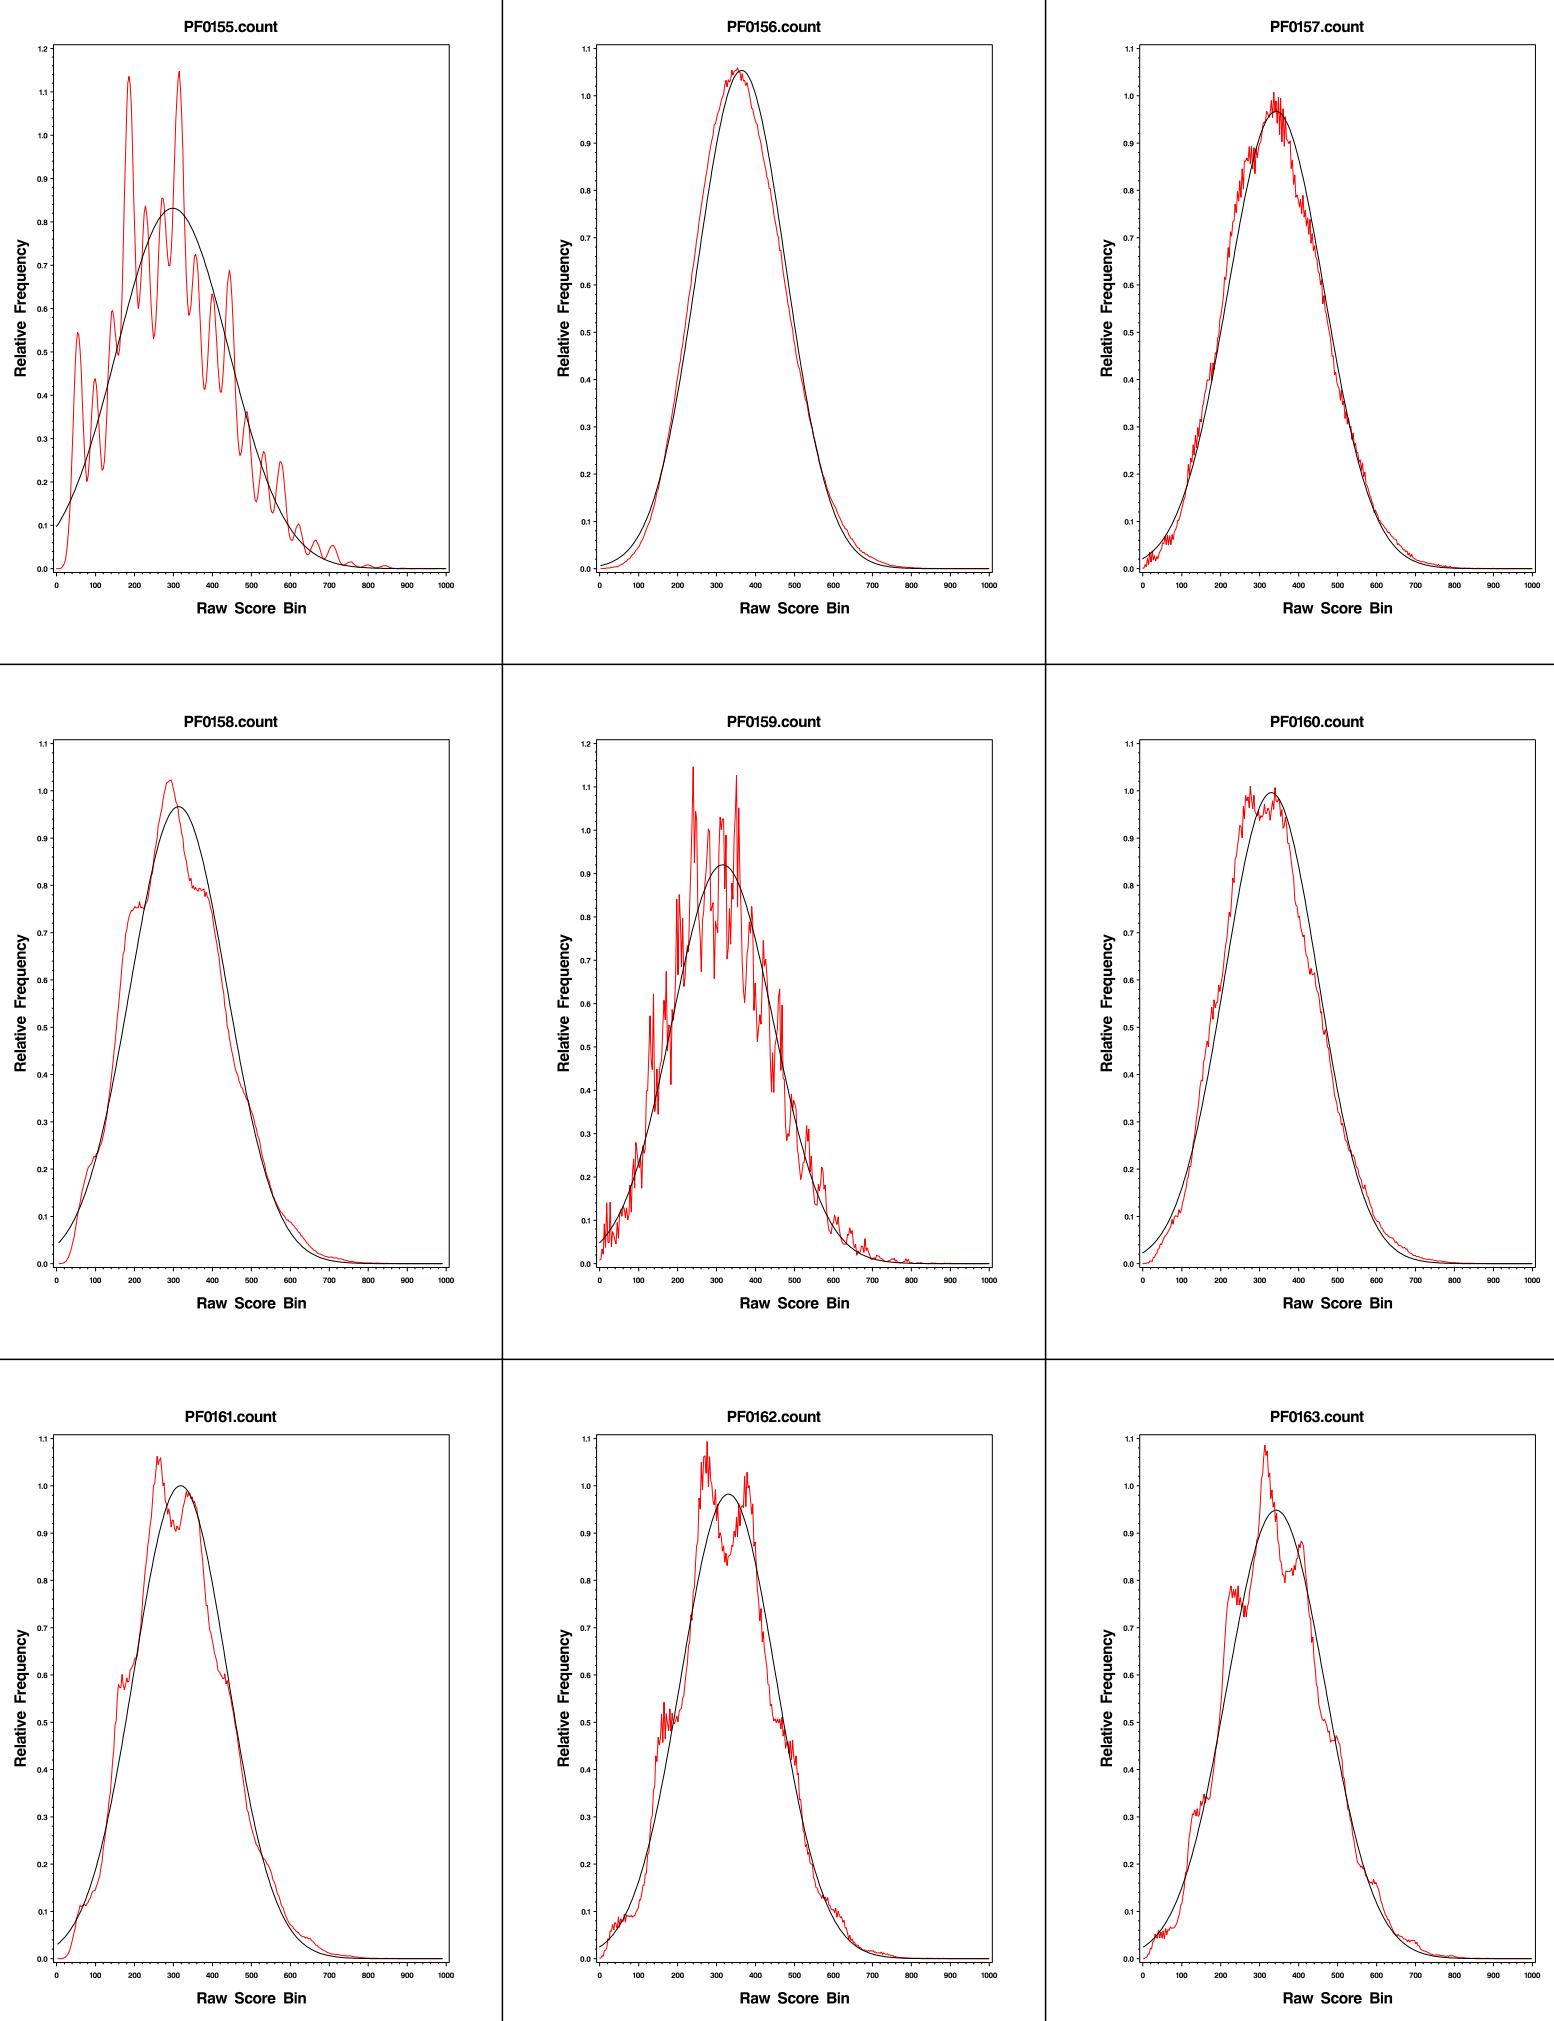

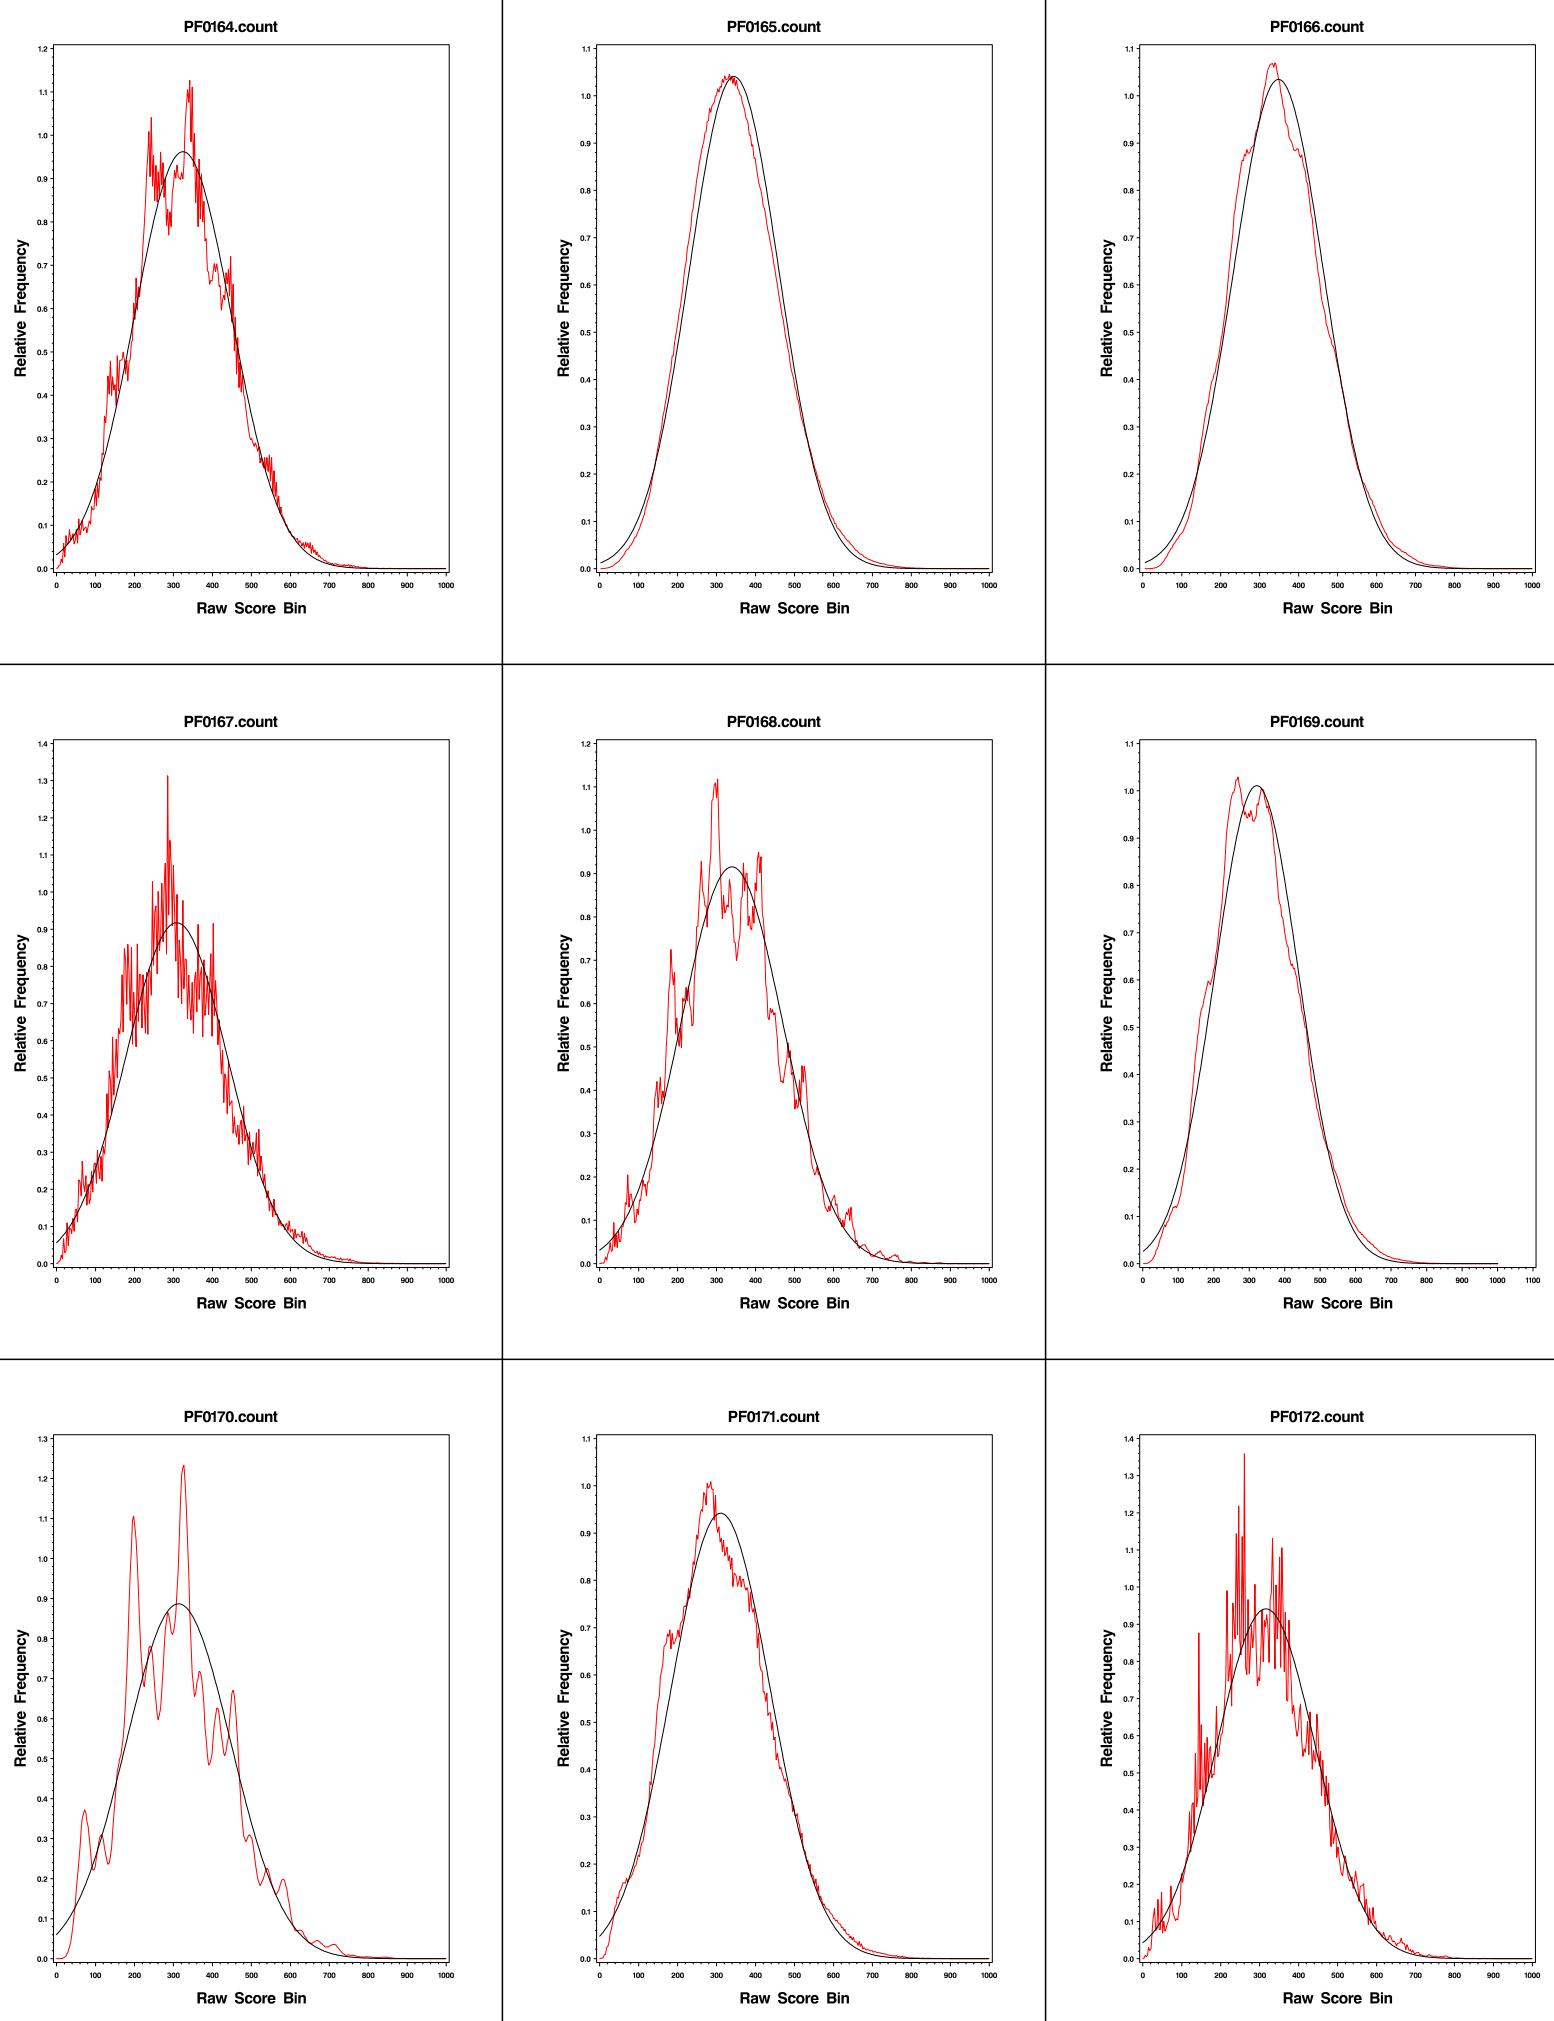

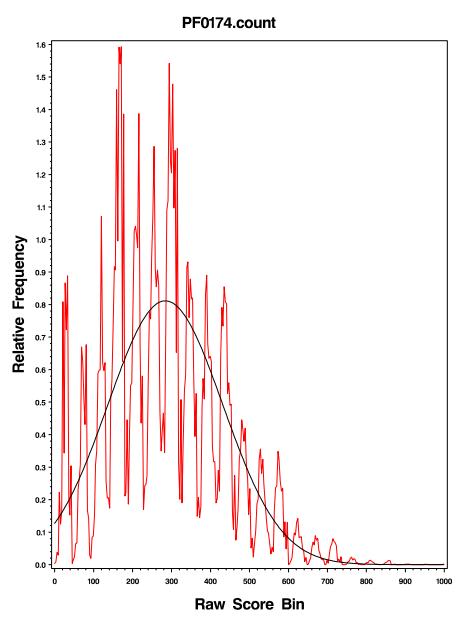

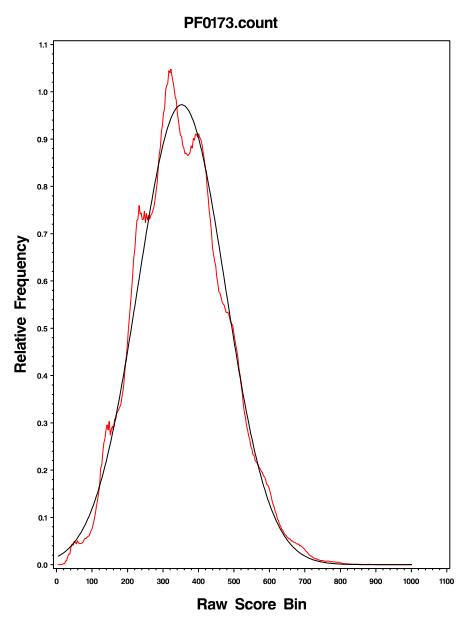

Table S2. Properties of raw score histograms for JASPAR TFBS matrices.
