

Mortality after *Aspergillus* infection

*Supplementary figure 1. The dependence of mortality on the number of *Aspergillus* conidia*

Immunosuppressed mice were randomly divided into five groups (20 mice per group). Animals in four groups were *Aspergillus* conidia infected, the non-infected group was the control. The number of conidia was $5 \cdot 10^4$, $2.5 \cdot 10^5$, $5 \cdot 10^5$, and $3.5 \cdot 10^6$. The survival of the animals were monitored 30 days after infection.
