Chemosensory genes

Chemosensation is the primary means by which most insects interrogate their environment and used for identifying e.g. hosts, mates as well as danger [1]. Compared to other insect genomes that were examined, we found a drastically reduced repertoire of chemosensory genes in *B. tabaci*, comprising only 7 and 17 odorant (OR) and gustatory (GR) receptor genes, respectively. In comparison, 79, 50 and 106 genes encode OR in the related Hemiptera *A. pisum*, *N. lugens*, and *R. prolixus*, respectively, while for GRs the numbers are 77, 10 and 28 [2, 3]. The number of genes encoding odorant binding proteins and chemosensory proteins in *B. tabaci*, 9 and 18 respectively, is likewise reduced compared to most other examined insect genomes, but similar to that of other Hemiptera [2]. The low number of genes encoding ORs is not wholly unexpected and in line with the observation that the antenna of *B. tabaci* only houses a handful of olfactory sensilla [4], which taken together with the genetic make-up suggests a reduced role for olfaction in this taxon. More unexpected is the low number of GRs. Compared to specialized species, polyphagous insects typically show expanded GR repertoires, particularly in genes encoding sensing of bitter tastes, which presumably reflect a need to identify a wider range of plant-produced toxins [5]. The low number of GRs in *N. lugens* may accordingly be a result of its specialized lifestyle and hence a limited need to differentiate and detect a large variety of toxins. Curiously, *B. tabaci* appears to have evolved a different strategy: rather than expanding the GR repertoire, it has instead increased the number of detoxification genes, thereby possibly rendering the need for detecting plant toxins of reduced importance.

Immune components and responses

The whitefly immune system is expected to be critical for recognizing and degrading microbial pathogens, while retaining beneficial endosymbionts. Orthologs of the key immune components of the TOLL, JAK-STAT, and JNK pathways were readily identified in the *B. tabaci* genome (**Additional file 19**). However, crucial components in the IMD pathway, such as *IMD*, *dFADD*, *Dredd*, and *Relish*, were not present. The IMD pathway mediates the humoral immune response against Gram-negative bacteria in *Drosophila melanogaster* [6]. This pathway is also incomplete in the genomes of other hemipteran insects, including *A. pisum*, *R. prolixus*, *D. citri* and *N.*

lugens, while being intact in the non-hemipteran insects including *Apis mellifera* (honey bee), *Anopheles gambiae* (mosquito) and *D. melanogaster* (fruit fly) (**Additional file 1: Figure S11**). In the *B. tabaci* genome, we found a single ortholog for the PGRP receptor family and five for the GGBP family, which are presumed to play central roles in recognition of bacteria and fungi. In addition, four antimicrobial peptides (AMPs) including thaumatin and defensin, were detected in the *B. tabaci* genome. Thus, the *B. tabaci* genome has a reduced immune repertoire as was found in the pea aphid genome [7], which may have facilitated the acquisition and maintenance of its microbial symbionts.

RNAi pathway

RNA interference (RNAi) is a conserved post-transcriptional gene silencing mechanism mediated by short interfering double-stranded RNA (dsRNA)-induced mRNA degradation in a variety of eukaryotic organisms. Gene silencing is induced by two partially overlapping pathways related to microRNA (miRNA) or small interfering RNA (siRNA) biogenesis. The *B. tabaci* genome possesses a single copy of most core genes in the miRNA pathway, including one copy of *dicer-1*, *ago-1*, *drosha*, *exportin-5*, *loquacious* and *pasha* (**Additional file 20**). Single copies of the core genes in the miRNA pathway were also observed in most other sequenced insect genomes [8, 9]. A previous study found a single copy of each siRNA pathway gene in *B. tabaci* based on transcriptome data [10]. In the *B. tabaci* genome, we identified single copies of *dicer-2* and *R2D2* but two copies of *ago-2* (**Additional file 20**). Interestingly, we identified 11 copies of RdRPs in the *B. tabaci* genome and several of these are more similar to virus RdRPs than to those found in other insects (**Additional file 1: Figure S12**).
