## **Appendix 1: Data sources**

### *Data inclusion and exclusion*

Data sources were included in NCD-RisC database if:

- measured data on systolic blood pressure (SBP) and/or diastolic blood pressure (DBP) were available;
- study participants were ten years of age and older;
- data were collected using a probabilistic sampling method with a defined sampling frame;
- data were from population samples at the national, sub-national (i.e. covering one or more sub-national regions), or community (one or a small number of communities) level;
- data were collected in or after 1950;
- data were from the countries and territories listed in Appendix Table 1.

We excluded all data sources that included only hypertension diagnosis history or medication status without measurement of blood pressure. We also excluded data sources on population subgroups whose blood pressure levels may differ systematically from the general population, including:

- studies that had included or excluded people based on their health status or cardiovascular risk;
- ethnic minorities;
- specific educational, occupational, or socioeconomic subgroups of the population; and
- those recruited through health facilities, with the exception noted below.

We used school-based data in countries where secondary school enrolment was 70% or higher, and used data whose sampling frame was health insurance schemes in countries where at least 80% of the population were insured. In addition, we used data collected through general practice and primary care system in high-income countries with universal insurance, because contact with the primary care systems tends to be at least as good as response rates for population-based surveys.

In this paper, we used data from the NCD-RisC database for years 1975 through 2015, and among subjects aged 18 years and older.

#### *Primary routes for data access*

We used a database of population-based data on cardiometabolic risk factors collated by the NCD Risk Factor Collaboration (NCD-RisC), a worldwide network of health researchers and practitioners whose aim is to understand the worldwide trends and variations in NCD risk factors. The initial database was collated through multiple routes for identifying and accessing data. We accessed publicly available population-based multi-country and national measurement surveys (e.g., Demographic and Health Surveys, and surveys identified via the Inter-University Consortium for Political and Social Research and European Health Interview & Health Examination Surveys Database) as well as the World Health Organization (WHO) STEPwise approach to Surveillance (STEPS) surveys. We requested, via WHO and its regional offices, from ministries of health and other national health and statistical agencies to identify and access population-based surveys. Requests were also sent via the World Heart Federation to its national partners. We made a similar request to the co-authors of an earlier pooled analysis of cardiometabolic risk factors,<sup>1-4</sup> and invited them to reanalyse data from their studies and join NCD-RisC. NCD-RisC database is continuously updated through the

above routes and through periodic requests to NCD-RisC members to help identify new data sources.

Anonymised individual record data from sources included in NCD-RisC were reanalysed by the Pooled Analysis and Writing Group or by data holders according to a common protocol. Within each survey, we included participants aged 18 years and older who were not pregnant. We dropped participants with implausible SBP (defined as SBP <70 mmHg or SBP >270 mmHg; 0.09% of all SBP data) or DBP (DBP <50 mmHg or DBP >150 mmHg; 0.07% of all DBP data).

We calculated mean SBP, mean DBP and prevalence of raised blood pressure defined as systolic blood pressure (SBP)  $\geq 140$  mmHg or diastolic blood pressure (DBP)  $\geq 90$  mmHg, and associated standard errors and sample sizes, by sex and age group (18-19 years, 20-29 years, followed by 10-year age groups and 80+ years). All analyses incorporated appropriate sample weights and complex survey design in calculating age-sex-specific means and prevalences when applicable. To ensure summaries were prepared according to the study protocol, the Pooled Analysis and Writing Group provided computer code to NCD-RisC members who requested assistance. All submitted data were checked by at least two independent members of the Pooled Analysis and Writing Group. Questions and clarifications were discussed with NCD-RisC members and resolved before data were incorporated in the database.

Finally, we obtained data not accessed through the above routes by extracting from published reports of all additional national health surveys identified through the above-described strategies, four sub-national STEPS surveys, 12 CINDI surveys, eight MONICA surveys

which were not deposited in MONICA Data Centre. We restricted the extractions to those reports that had reported data by sex and in age groups no wider than 20 years. We also used data from a previous pooling study<sup>2</sup> when such data did not overlap with those accessed through the above routes.

#### *Secondary search for additional data sources*

To identify any major sources not accessed through the above routes, we searched Medline (via PubMed) for articles published between 1<sup>st</sup> January 1950 and 19<sup>th</sup> February 2014 using the search terms ("blood pressure"[Mesh:NoExp] OR "hypertension"[Mesh:NoExp]) AND ("Humans"[Mesh]) (search for adults for articles published between 1980 and 2009 was done in a previous analysis;<sup>2</sup> those for children for all years and for adults for years prior to 1980 and after 2009 were done here). We excluded the USA from the search because multiple nationally representative health examination surveys with individual records were publicly accessible and accessed before the search had begun. Articles identified through this search were screened according to the inclusion and exclusion criteria described above. The number of articles identified and retained is summarised in Appendix Figure 1. We contacted the corresponding authors of all eligible studies and invited them to join NCD-RisC. We did similar searches for other cardiometabolic risk factors including body mass index (BMI),<sup>5</sup> height,<sup>6</sup> diabetes,<sup>7</sup> and serum cholesterol. All eligible studies were invited to analyse data on all cardiometabolic risk factors and join NCD-RisC.

#### *Data management*

For each data source accessed through the primary and secondary data access process, we recorded the available information about the study population, period of measurement, sampling approach, and measurement methods. The information about study population was

used to establish that each data source was population-based, and to assess whether it covered the whole country, multiple sub-national regions, or one or a small number of communities, and whether it was rural, urban, or combined.

We carefully checked all data sources in terms of how they met our inclusion and exclusion criteria. We identified duplicate data sources by comparing studies from the same country and year. Additionally, NCD-RisC members received the list of all data sources in the database and were asked to ensure that the included data from their country met the inclusion criteria and that there were no duplicates. Data sources used in the analysis are listed in Appendix Table 2.

## **Appendix 2:** Converting to primary blood pressure metrics

As described in Methods, our primary outcomes were mean SBP, mean DBP and prevalence of raised blood pressure defined as  $SBP \geq 140$  mmHg or  $DBP \geq 90$  mmHg, which were all available for 80% of data sources (84% of age-sex specific data points). Of the other 16% data points, from a previous global pooling<sup>2</sup> or extracted from published studies, 6% had mean SBP but not the other two primary outcomes; 6% had both mean SBP and mean DBP but not prevalence of raised blood pressure; 1% had only prevalence of raised blood pressure as defined above, and the remaining 3% had only a prevalence that differed from raised blood pressure defined above, e.g.  $SBP \geq 160$  mmHg or  $DBP \geq 95$  mmHg, or one that included use of antihypertensive medicine in the definition. In order to use these data, we developed conversion regressions to estimate the missing or all three primary outcomes from the data available.

The dependent variable in each regression was one of our primary outcomes, and the main independent variable was one or more of the above-mentioned metrics present in at least one study that did not report all three primary outcomes. The coefficients of these regressions were estimated from data sources with individual-level data which could be used to calculate all included terms, excluding data points for which there were fewer than 25 subjects. All regressions included terms for age, sex, country's income (natural logarithm of per-capita gross domestic product in 2011 international dollars), and the year of study, and regional random effects. Finally, we included interaction terms in the regressions if the interaction terms provided a better fit to the data as determined by the Bayesian Information Criteria (BIC).<sup>8</sup> In all cases, all sources of uncertainty in the conversion – including the sampling uncertainty of the original data, the uncertainty of the regression coefficients and random effects, and residuals – were carried forward by using repeated draws from their respective

distributions while accounting for the correlation among the uncertainties of regression coefficients and random effects. The regression coefficients and number of data points used to estimate the coefficients are shown in Appendix Table 3.

### **Appendix 3: Model covariates**

As stated in the main paper, our statistical model included covariates that help predict blood pressure, including average number of years of education, proportion of national population living in urban areas, and a summary measure of availability of different food types for human consumption.

Data on proportion of national population living in urban areas were from the United Nations Population Division for all countries in our analysis. Data on average number of years of education were from the Institute of Health Metrics and Evaluation Global Educational Attainment for 190 countries. We used regional averages for American Samoa, Cook Islands, Greenland, St Kitts & Nevis, Niue, Nauru, Palau, French Polynesia, Tokelau and Tuvalu. The covariate on food availability was constructed from the food balance sheets of the Food and Agriculture Organization of the United Nations, using principal component analysis of 19 food items (alcoholic beverages, animal fats, cereals, eggs, fish & seafood, fruits (excluding wine), meat, milk (excluding butter), offals, oilcrops, other aquatic products, pulses, spices, starchy roots, stimulants, sugar & sweeteners, treenuts, vegetable oils and vegetables) as described elsewhere.<sup>2,9,10</sup>

Before the principal component analysis, the data for all country-item pairs were examined manually for outliers and implausible values. We removed six country-item-year data points as outliers, and 322 as implausible, mostly from the Maldives and Namibia. In addition, we removed all data for Occupied Palestinian Territory because the pre-1996 data were implausibly low. After data cleaning, a total of 2,283 country-item-year data points (~1% of all country-item-year data points for 179 countries with data) were missing. 38% of these were for non-fish aquatic products (e.g., aquatic mammals) and were set to zero as this item

was zero in most countries with data. Another 49% were situations in which a part of the time series was missing in such a way that missing years can be filled through linear interpolation or linear extrapolation using the regional linear trends. For the remaining 13%, regional means were used. Finally, we used regional means for 21 countries without data (American Samoa, Andorra, Bahrain, Bhutan, Cook Islands, DR Congo, Equatorial Guinea, Federated States of Micronesia, Greenland, Marshall Islands, Nauru, Niue, Oman, Palau, Papua New Guinea, Puerto Rico, Qatar, Singapore, Tokelau, Tonga and Tuvalu).

#### **Appendix 4: Validation of statistical model**

We tested how well our statistical model, which is described in the main text, predicts mean blood pressure and prevalence of raised blood pressure in countries and years without data in two different tests. In Test 1, we held out all data from 10% of countries with data (i.e., created the appearance of countries with no data where we actually had data). The countries whose data were withheld were randomly selected from the following three groups: data-rich (6 or more data sources, with at least one year of data after 2000), data-poor (1 data source), and average data availability (2 to 5 data sources, or 6 or more data sources with no data after 2000). We fitted the model to the data from the remaining 90% of countries and made estimates of the held-out observations. In Test 2, we assessed other patterns of missing data by holding out 10% of our data sources, again from a mix of data-rich, data-poor, and average-data countries, as defined above. For a given country, we either held out a random one third of the country's data or all of the country's 2000-2015 data to determine, respectively, how well we filled in the gaps for countries with intermittent data and how well we estimated in countries without recent data. We fitted the model to the remaining 90% of the dataset and made estimates of the held-out observations. We repeated each test five times, holding out a different subset of data in each repetition. In both tests, we calculated the differences between the held-out data and the estimates. We also checked the 95% credible intervals of the estimates; in a model with good external predictive validity, 95% of held-out values would be included in the 95% credible intervals.

Our statistical model performed well in the validation tests. The estimates of raised blood pressure prevalence were unbiased as evidenced with median errors that were very close to zero globally (ranging from -0.6 percentage points to 0.9 percentage points for the two sexes in the two tests), and less than or equal to  $\pm 4$  percentage points in every subset of withheld

data except the -10.0 and -4.7 percentage points differences in Test 1 in South Asia for men and women respectively, and 4.9 percentage points difference in Test 1 for women in Central and Eastern Europe (Appendix Table 4). The 95% credible intervals of estimated prevalence covered 96-98% of true data, which implies good estimation of uncertainty; among all subgroups of data, coverages were  $\geq 90\%$  for both sexes. Median absolute errors ranged from 5.1 to 7.2 percentage points overall, or 2.2 to 10.2 percentage points in all subsets of withheld data.

Median errors for mean SBP and DBP were also small, and ranged from 0.10 to 0.99 mmHg for mean SBP and -0.07 to 0.50 mmHg for mean DBP globally suggesting that our estimates of mean SBP and DBP are also on average unbiased (Appendix Table 4). They were small in all subsets of withheld data: less than  $\pm 3$  mmHg for mean SBP, with two exceptions (women in high-income Asia Pacific, a super-region with only three countries one of which was held out, and in Central and Eastern Europe) in Test 1; less than or equal to  $\pm 2$  mmHg for mean DBP, also with two exceptions in Test 1 (men in South Asia and women in Central and Eastern Europe). Median absolute errors ranged from 3.5 to 4.4 mmHg for mean SBP and 2.2 to 2.8 mmHg for mean DBP overall, or less than 6 mmHg for mean SBP (except 8.3 mmHg in high-income Asia Pacific for women in Test 1) and less than or equal to 3.6 mmHg for mean DBP (except 4.3 mmHg for men in South Asia and 4.0 mmHg for women in Central and Eastern Europe in Test 1) in all subsets. Coverage globally for SBP was 86-88% in Test 1 and 74-77% in Test 2. In subsets, coverage ranged from 66% to 96%, but was mostly  $>75\%$ , with coverage generally lower in Test 2 than Test 1. For DBP, global coverage was 87-88% in Test 1 and 78-79% in Test 2. In subsets, coverage ranged from 72% to 98%, but was mostly  $>80\%$ , with coverage again generally lower in Test 2 than Test 1.

For comparison, median absolute differences between pairs of nationally representative surveys done in the same country and in the same year were 2.1 mmHg for SBP, 1.5 mmHg for DBP and 3.2 percentage points for prevalence of raised blood pressure, indicating that our estimates perform as well as running two parallel surveys in the same country and year.

Nonetheless the prediction errors were slightly larger and coverage lower than similar analyses for BMI and height (but not compared to diabetes),<sup>5-7</sup> likely because blood pressure varies more across countries in the same region than BMI and height, and because its trends over time are more complex and may include periods when blood pressure is unchanged preceding or following rises or declines in the same country. This heterogeneity makes prediction in countries and years without data harder than in the case of BMI and height, where there has been more steady change in most countries and where within-region variation is smaller.

**Appendix Table 1:** List of analysis regions and “super-regions”, and countries in each region. The hierarchical structure of the statistical model consisted of country, region, super-region, and world.

<b>Super-region</b>	<b>Region</b>
<b>Sub-Saharan Africa (48)</b>	<b>Central Africa (6):</b> Angola, Central African Republic, Congo, DR Congo, Equatorial Guinea, Gabon
	<b>East Africa (17):</b> Burundi, Comoros, Djibouti, Eritrea, Ethiopia, Kenya, Madagascar, Malawi, Mauritius, Mozambique, Rwanda, Seychelles, Somalia, Sudan, Tanzania, Uganda, Zambia
	<b>Southern Africa (6):</b> Botswana, Lesotho, Namibia, South Africa, Swaziland, Zimbabwe
	<b>West Africa (19):</b> Benin, Burkina Faso, Cabo Verde, Cameroon, Chad, Cote d'Ivoire, Gambia, Ghana, Guinea, Guinea Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Sao Tome and Principe, Senegal, Sierra Leone, Togo
<b>Central Asia, Middle East and North Africa (28)</b>	<b>Central Asia (9):</b> Armenia, Azerbaijan, Georgia, Kazakhstan, Kyrgyzstan, Mongolia, Tajikistan, Turkmenistan, Uzbekistan
	<b>Middle East and North Africa (19):</b> Algeria, Bahrain, Egypt, Iran, Iraq, Jordan, Kuwait, Lebanon, Libya, Morocco, Occupied Palestinian Territory, Oman, Qatar, Saudi Arabia, Syrian Arab Republic, Tunisia, Turkey, United Arab Emirates, Yemen
<b>South Asia (6)</b>	<b>South Asia (6):</b> Afghanistan, Bangladesh, Bhutan, India, Nepal, Pakistan
<b>East and Southeast Asia (16)</b>	<b>East Asia (4):</b> China, China (Hong Kong SAR), North Korea, Taiwan
	<b>Southeast Asia (12):</b> Brunei Darussalam, Cambodia, Indonesia, Lao PDR, Malaysia, Maldives, Myanmar, Philippines, Sri Lanka, Thailand, Timor-Leste, Viet Nam
<b>Oceania (17)</b>	<b>Polynesia and Micronesia (13):</b> American Samoa, Cook Islands, French Polynesia, Kiribati, Marshall Islands, Micronesia (Federated States of), Nauru, Niue, Palau, Samoa, Tokelau, Tonga, Tuvalu
	<b>Melanesia (4):</b> Fiji, Papua New Guinea, Solomon Islands, Vanuatu
<b>High-income Asia Pacific (3)</b>	<b>High-income Asia Pacific (3):</b> Japan, Singapore, South Korea
<b>Latin America and Caribbean (35)</b>	<b>Andean Latin America (3):</b> Bolivia, Ecuador, Peru
	<b>Caribbean (18):</b> Antigua and Barbuda, Bahamas, Barbados, Belize, Bermuda, Cuba, Dominica, Dominican Republic, Grenada, Guyana, Haiti, Jamaica, Puerto Rico, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines, Suriname, Trinidad and Tobago
	<b>Central Latin America (9):</b> Colombia, Costa Rica, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Venezuela
	<b>Southern Latin America (5):</b> Argentina, Brazil, Chile, Paraguay, Uruguay
<b>High-income Western countries (27)</b>	<b>High-income English-speaking countries* (6):</b> Australia, Canada, Ireland, New Zealand, United Kingdom, United States of America
	<b>North Western Europe (12):</b> Austria, Belgium, Denmark, Finland, Germany, Greenland, Iceland, Luxembourg, Netherlands, Norway, Sweden, Switzerland
	<b>South Western Europe (9):</b> Andorra, Cyprus, France, Greece, Israel, Italy, Malta, Portugal, Spain

<b>Central and Eastern Europe (20)</b>	<b>Central Europe (13):</b> Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, Hungary, Macedonia (TFYR), Montenegro, Poland, Romania, Serbia, Slovakia, Slovenia
	<b>Eastern Europe (7):</b> Belarus, Estonia, Latvia, Lithuania, Moldova, Russian Federation, Ukraine

\* Although high-income English-speaking countries are geographically separated, they exhibit remarkably similar trends in cardiometabolic risk factors and outcomes.<sup>5-7</sup> They were therefore grouped together so that the statistical model shares information amongst them more than it does with other countries that are geographically closer but epidemiologically more distinct.

We did not have data on population by age group for American Samoa, Bermuda, French Polynesia, Greenland, and Tokelau. Country-specific estimates were made but were not used in calculation of regional and global prevalences because the latter requires weighting by age-specific population.

**Appendix Table 2:** Data sources used in the analysis.

1. Blood pressure measurement devices include:

'Standard': standard mercury sphygmomanometer or aneroid sphygmomanometer; 'Random-zero': random-zero mercury sphygmomanometer; 'Digital': digital oscillometric device; 'Unknown': information unavailable or multiple types of devices used.

2. The first age group started from <18 years old, but had a mean age ≥18 years.

3. This research uses data from China Health and Nutrition Survey (CHNS). We thank the National Institute of Nutrition and Food Safety, China Center for Disease Control and Prevention, Carolina Population Center (5 R24 HD050924), the University of North Carolina at Chapel Hill, the NIH (R01-HD30880, DK056350, R24-HD050924, and R01-HD38700) and the Fogarty International Center, NIH for financial support for the CHNS data collection and analysis files from 1989 to 2011 and future surveys, and the China-Japan Friendship Hospital, Ministry of Health for support for CHNS 2009.

4. National study conducted between 1972 and 1974, included in the analysis as a 1975 study.

**Appendix Table 3:** Model specifications and regression coefficients to estimate the primary outcomes (mean SBP, mean DBP, and prevalence of raised blood pressure defined by SBP  $\geq 140$  mmHg or DBP  $\geq 90$  mmHg) from other metrics.

The dependent variable in all regressions was inverse of means or prevalence, fitted using a linear (mixed) model for means and a generalized linear (mixed) model with a probit link function for prevalence. Random effects for regions are presented.

\* denotes statistical interaction. CI: confidence interval.

<b>Primary outcome: mean SBP</b>	
<b>Independent variable: prevalence (SBP <math>\geq</math>140 mmHg or DBP <math>\geq</math>90 mmHg)</b>	
<b>Variables</b>	<b>Coefficients (95% CI)</b>
Intercept	0.0074 (0.0074, 0.0075)
Probit-transformed prevalence (SBP $\geq$ 140 mmHg or DBP $\geq$ 90 mmHg)	-0.00095 (-0.00096, -0.00094)
Mean age of age group (centred at 50 years)	-6.2e-06 (-6.6e-06, -5.9e-06)
Male sex	9.4e-06 (-3.1e-08, 1.9e-05)
Study mid-year (per one more recent year since 1975)	-1.8e-06 (-2.3e-06, -1.4e-06)
Natural logarithm of per-capita gross domestic product	-5.8e-06 (-1.3e-05, 1.6e-06)
Probit-transformed prevalence * mean age of age group	-5.5e-06 (-5.8e-06, -5.2e-06)
Probit-transformed prevalence * male sex	0.00016 (0.00015, 0.00017)
Random effects for regions	Yes
<b>Number of data points used to fit the model = 10,517</b>	

Traditional  $R^2$  is not clearly defined for mixed-effect models. The conditional  $R^2$  for the model, which describes the proportion of variance explained by both fixed and random factors,<sup>11</sup> was 0.924.

<b>Primary outcome: mean SBP</b>	
<b>Independent variable: prevalence (SBP <math>\geq</math>140 mmHg)</b>	
<b>Variables</b>	<b>Coefficients (95% CI)</b>
Intercept	0.0073 (0.0072, 0.0074)

† Estimated values minus held out values.

\* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

**Appendix Table 5:** Mean systolic blood pressure, mean diastolic blood pressure and prevalence of raised blood pressure by sex and age group for the world and nine super-regions in 1975, 1985, 1995, 2005 and 2015. Numbers in brackets show 95% credible intervals.

MENA: Middle East and North Africa
