## APPENDIX FIGURE LEGENDS

### **Appendix Figure S1. Two Oct4/Oct6 linker alignments result in a different reprogramming efficiency with the Oct4<sup>LinkO6</sup> mutant.**

**A.** Two sequence alignments of POU linker regions of Oct4 and Oct6. On the left, first sequence alignment used by Esch and coworkers [44]. On the right, a structural alignment of the Oct4 and Oct6 linker sequences is shown. In the structural alignment, the entire RK motifs are aligned with a central gap (see Appendix Fig. S1B), thus shifting the position of the first Arg residue in the Oct6 RK motif by one position compared to the sequence based alignment. Prominent residues are highlighted by their number in the sequence.

**B.** Structural model illustrating the difference between Oct4 (green) and Oct6 (orange) RK motifs, which follow the linkers. The “gap” points to the region where Oct4 lacks one positive charge compared with Oct6. This region is also marked by a blue arrow in the structural alignment in panel A of this Figure. Additionally, residue 40 of the POU<sub>s</sub> (Lys in Oct4 and Gln in Oct6) is marked with an asterisk. This residue comes close to the RK region after the linker and adds one positive charge to the construct used in Esch and coworkers [44].

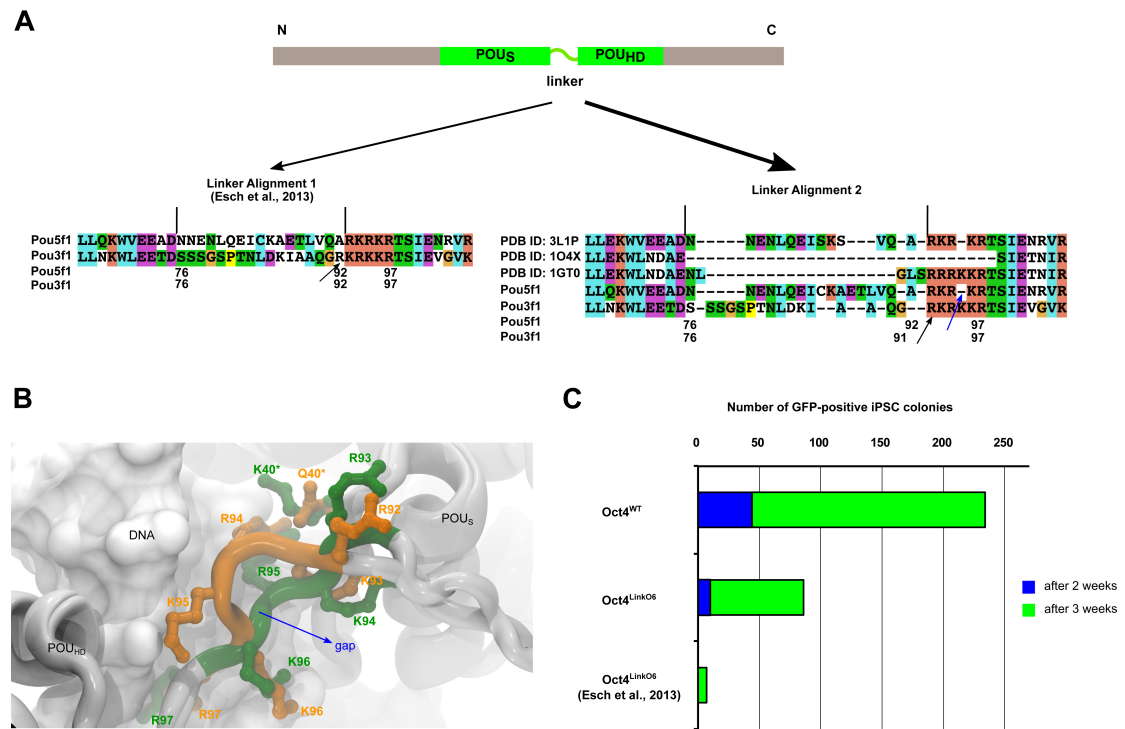

**C.** Comparison of reprogramming efficiencies using WT Oct4 TF and the two Oct4<sup>LinkO6</sup> mutants—first based on the new structural alignment presented here (excluding the Arg residue) and second using the alignment used by Esch and coworkers (including the Arg residue; n=1).

### **Appendix Figure S2. Transgene expression and illustration of colony counting.**

**A.** The relative transcript levels of Oct4 and its mutants were analyzed by qRT-PCR. Viral supernatants from reprogramming experiments performed side-by-side are shown as mean +/- standard deviation (n=2).

**B.** Representative images of GFP-positive colonies (at 2.5x magnification) generated by WT Oct4 and its mutants in combination with Sox2, Klf4, and c-Myc. Colonies were counted 16 days after viral infection, using a fluorescence microscope. GFP signals considered independent colonies are marked with dashed circles. Scale bars: 500  $\mu$ m.
