## **TEXT 2: Definition and classification of AF in the included studies**

### **1. ACTIVE-W<sup>21</sup>**

Patients were classified as having paroxysmal, persistent, or permanent AF by local investigators. Patients with permanent AF had electrocardiogram-documented AF at the time of enrollment and no evidence of SR in the 6 months before randomization. Patients with paroxysmal or persistent AF may not have been in AF at the time of randomization, but had electrocardiogram-documented AF on 2 separate occasions, at least 2 weeks apart, in the 6 months before randomization.

### **2. ARISTOTLE<sup>16</sup>**

The definitions of paroxysmal, persistent, and permanent AF used in the trial were in accordance with the definitions used in the 2006 American College of Cardiology/American Heart Association/European Society of Cardiology AF guidelines. Specifically, paroxysmal AF was defined as recurrent AF that terminates spontaneously, persistent AF was defined as AF that is sustained beyond 7 days, and permanent AF was defined as long-standing AF in which restoring and/or maintaining sinus rhythm has failed or has been foregone. The prior need for a cardioversion did not automatically lead to classifying AF as persistent; the subsequent occurrence of self-terminating paroxysms of AF in such patients led to classifying them as having paroxysmal AF. The type of AF was classified by the sites at randomization when they had to specify whether a particular patient had paroxysmal or persistent/permanent (combined into one category) AF or atrial flutter documented by an ECG at the time of enrolment or whether a patient had AF or atrial flutter documented on two separate occasions at least 2 weeks apart in the 6 months prior to enrolment.

### **3. AVERROES<sup>22</sup>**

Patients had AF documented by 12-lead electrocardiography (ECG) on the day of screening. If not in AF on the day of screening, AF had to be documented in the 6 months prior to enrolment by 12-lead ECG or as an episode at least 5 min in duration on a rhythm strip or Holter recording. Pacemaker or ICD electrogram recordings could be used to document AF but the duration of AF had to be at least 30 min if this was the only documentation of AF.

Patients were classified as having paroxysmal, persistent or permanent AF at baseline by local investigators. Patients with permanent AF had ECG documented AF at the time of enrolment and no evidence of sinus rhythm (SR) in the 6 months prior to randomization. Patients with paroxysmal or persistent AF may not have been in AF at

the time of randomization, but had ECG documented AF in the 6 months prior to randomization.

#### **4. RE-LY<sup>32</sup>**

AF is documented by ECG on the day of screening or randomization. The patient has had a symptomatic episode of paroxysmal or persistent AF documented by 12-lead ECG within 6 months before randomization. There is documentation of symptomatic or asymptomatic paroxysmal or persistent AF on 2 separate occasions, at least 1 day apart, one of which is within 6 months before randomization. In this case, AF may be documented by 12 lead ECG, rhythm strip, pacemaker/ICD electrogram, or Holter ECG. The duration of AF should be at least 30 s. Electrograms (not marker channels or mode switch episodes) from pacemakers and defibrillators can be used to document only 1 episode of paroxysmal or persistent AF.

#### **5. ROCKET-AF<sup>17</sup>**

All the patients had to have electrocardiographic evidence of AF within 30 days prior to randomization; additionally, they had to have medical evidence of AF within the previous year. Patients were categorized by the enrolling physician at baseline as having either paroxysmal (lasting  $\leq 7$  days at any time) or persistent AF ( $>7$  days at a time); no other AF types were provided as choices.

#### **6. SPORTIF III-V<sup>13</sup>**

AF was defined as paroxysmal or persistent nonvalvular AF verified by at least two ECG recordings, one of which was made within 2 weeks before randomization. The “persistent (constant)” AF was made by the study investigator prior to randomization based on baseline ECG recordings and prior clinical history. Thus, those categorized as “persistent (constant)” AF would include those with persistent or permanent AF. Whilst the categorization depended upon investigator classification, the diagnosis would have been verified by the trial monitors review of source documents.

## A. Stroke or non-CNS systemic embolism

## B. Major bleeding

**FIGURE 1.** Efficacy (A) and safety (B) outcomes of paroxysmal vs. sustained AF according to treatments of NOACs and warfarin. AF=atrial fibrillation, df=degrees of freedom, M-H=Mantel-Haenszel, NOACs=novel oral anticoagulants.

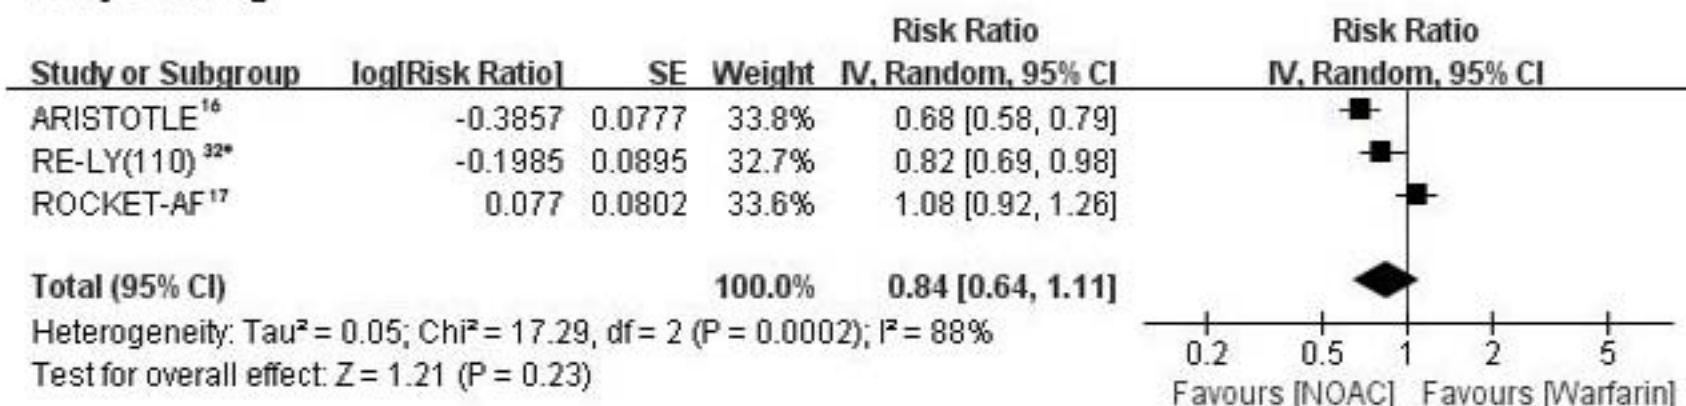

## A. Sustained AF

### a. Stroke or non-CNS systemic embolism

### b. Major bleeding

## B. Paroxysmal AF

### a. Stroke or non-CNS systemic embolism

### b. Major bleeding
