| HOMA-insulin resistance index ² | 1.9 | 4.0 | 9.7 | 87.5 | 0.389* |

The number of participants with both metabolite data and fatty liver measurements was n=2,002. Since some metabolic measures were not determined in a small number of study participants, for some measures, the concentrations are reported for n=1,939–2,002.

Abbreviations: DHA, docosahexaenoic acid; HDL, high-density lipoprotein; HOMA, homeostatic model; IDL, intermediate-density lipoprotein; LDL, low-density lipoprotein; MUFA, monounsaturated fatty acid; PUFA, polyunsaturated fatty acid; SFA, saturated fatty acid; VLDL, very-low-density lipoprotein.

¹Spearman correlation coefficients between absolute metabolite concentrations and the categorical fatty liver score (n=1,859–1,919). The fatty liver score was calculated by summarizing the values of the five widely accepted criteria for fatty liver: 1) the liver-to-kidney contrast (no=0 or clear contrast=1), 2) parenchymal brightness (normal=0, mild=1, intermediate=2 or severe brightness=3), 3) deep beam attenuation (clear=0, attenuated=1 or no visible=2 line of diaphragm) 4) bright vessel walls (normal=0, partly visible=1 or no visible=2 vessel walls) and 5) visibility of the neck of the gallbladder (normal=0, partly visible=1, not visible=2). The final score included in values ranging from 0 to 9.

²Measure not quantified by the NMR metabolomics platform.

* Statistical significance at $P<0.0007$.

SUPPLEMENTARY TABLE 2: Comparison of BMI and waist circumference as anthropometric covariates in the cross-sectional (metabolites in 2011 vs. fatty liver status in 2011) and prospective (metabolites in 2001 vs. fatty liver status in 2011) associations. Odds ratios and their 95% confidence intervals are per 1-SD increment in the metabolic measures, and shown with adjustment for sex, age, BMI or waist circumference, alcohol intake, leisure-time physical activity and smoking.

Cross-sectional associations included in 1,939–2,002 individuals of whom 339–372 had diagnosed fatty liver in 2011. Prospective associations included in 1,516–1,575 individuals with metabolite data at the 2001-baseline, of whom 263–275 had fatty liver diagnosed in 2011.

Prior to prospective analyses, individuals with suspected fatty liver in 2001 were excluded (alanine aminotransferase > 30 U/L).

P-values in the exponential format denote metabolite associations that were statistically significant associations when accounting for Bonferroni-correction ($P<0.0007$).

DHA, docosahexaenoic acid; HDL, high-density lipoprotein; HOMA-IR, homeostatic model-based insulin resistance index; IDL, intermediate-density lipoprotein; LDL, low-density lipoprotein; MUFA, monounsaturated fatty acid; PUFA, polyunsaturated fatty acid; SFA, saturated fatty acid; VLDL, very-low-density lipoprotein.

SUPPLEMENTARY FIGURE 1: Prospective associations of metabolic measures with 4-year risk for fatty liver ($n=1,455-1,509$ with metabolite data at the 2007-survey, of whom 207-212 had fatty liver diagnosed in 2011). Odds ratios (95% confidence intervals) are per 1-SD increment in the metabolic measures, and shown with adjustment for sex and age (blue), and additionally for baseline waist, alcohol intake, leisure-time physical activity and smoking (red). P-values listed in exponential format denote metabolite associations that were statistically significant associations when accounting for Bonferroni-correction ($P<0.0007$). Individuals with suspected fatty liver in 2007 (alanine aminotransferase > 30 U/L) were excluded from analyses.
