33 **Supplementary Data**

34 **Methods**

35 **Homology Modelling using MODELLER v9.1**

36 Comparative modelling involves four main steps³⁴ (see Supplementary Fig. S2 online),
37 which are as follows:

- 38 a. Template screening, identification and initial alignment – The protein template is
39 selected from the PDB with the help of psiBLAST.
- 40 b. Final template selection and alignment – The final template is selected among all
41 available templates based upon the % identity and E-value.
- 42 c. Model Building – The model is built by aligning the query sequence (NP_006352.2)
43 against the template structures.
- 44 d. Model Evaluation and Selection – The generated models are evaluated for the low
45 DOPE score ad high GA341 Score to prove it as the best model.
- 46 e. Model Validation – The evaluated and the selected model are validated for their
47 features and properties with the help of the Ramachandran Plot³⁶ and PDBsum.

48 **Sequence format conversion**

49 The *HOXB13* protein sequence (NP_006352) obtained from NCBI needs to be first
50 converted to a file format, which can be read and processed by MODELLER v9.1. The sequence
51 was converted to a PIR file format. Similar to the FASTA format the PIR file format also
52 consists of a header denoted by >P1 followed by the sequence identifier and details. The PIR file
53 format contains the single letter standard amino acid codes with “*” in the end denoting the end
54 of the protein sequence. The converted sequence in the PIR format was saved as “hoxb13.ali”.

55 **Target Template identification and initial alignment**

56 A suitable template structure for developing the model was obtained using psiBLAST by
57 setting PDB as the source database⁶⁶ for finding 3D structure templates. The resulting sequences
58 of at least >30% similarity and identity were picked for comparative homology modelling. The
59 Supplementary Table S8 online shows the results of psiBLAST. PDB ID 2CRA was found to
60 have 100% identity with the query sequence and PDB ID 2LD5 and 2L7Z showed 78% identity
61 with the query sequence and were chosen as the template for modelling the *HOXB13* protein.
62 The respective “.pdb” files of the above-mentioned proteins were downloaded and kept in the
63 same folder where the python script files were located. These three PDB ID structures – 2CRA,

64 2LD5 and 2L7Z were used as the template for modelling the complete *HOXB13* protein using
65 comparative homology modelling by MODELLER v9.17. The distance tree of the query
66 sequence and the protein structures from the PDB computed by psiBLAST can be found as
67 Supplementary Fig. S4 online.

68 **Final template selection**

69 From the three chosen PDB structures (2CRA, 2LD5 and 2L7Z), the most appropriate
70 structure for the query sequence (NP_006352 – *HOXB13*) was chosen by the
71 “alignment.compare_structures()” command from MODELLER v9.17 to analyze the structural
72 and sequence similarity between the template structures (2CRA, 2LD5 and 2L7Z) and the query
73 sequence (NP_006352). The Python script for the final template selection was saved as
74 “script2.py”. The contents of the “script2.py” were given in the supplementary data. The
75 “compare_structure” command mainly compares the RMS deviation, dihedral angles of the main
76 and side chain atoms, identities, similarities, etc., between the sequence and the structure. We
77 used this command and to generate the “dendrogram” with distance matrix for analyzing and
78 selecting the best template among the three targets. The results were logged in the “script2.log”
79 file. From the results, we found that 2LD5 and 2L7Z were both structurally and sequentially
80 identical with the same crystallographic resolution of 1.0Å (as Supplementary Fig. S5 online).
81 Conversely, the structure 2CRA was found to be diversified from both 2LD5 and 2L7Z with a
82 distance score of 63.5. Hence, the structure 2L7Z was finally selected for modelling of complete
83 *HOXB13* because of its high sequence and structural similarity to the query sequence.

84 **Aligning the template 2L7Z with the query sequence (NP_006352)**

85 The alignment of the query sequence (NP_006352) with the template structure 2L7Z was
86 done with the help of the “align2d()” command in MODELLER v9.17. The alignment algorithm
87 used by the MODELLER v9.17 at this step was different from the other normal sequence
88 alignment algorithms, since, in this case, alignment was being carried out between the sequence
89 and the structure information. This was done with the help of the gap penalty function so that
90 there was a greater reduction in the alignment errors when compared to other standard sequence-
91 sequence alignment algorithms. The Python script for the alignment was saved as “script3.py”.
92 The detailed contents of the “script3.py” were furnished in the supplementary data section. The
93 “align2d()” command aligned the query sequence saved in PIR format as “hoxb13.ali” file with
94 the template protein structure file saved as “2l7z.pdb”.

95 The results were logged in the “script3.log” file, and the alignment was generated as
96 “hoxb13-2l7z.pap” and “hoxb13-2l7z.ali” files. All the identical positions were marked with “*
97 ”. The output of the alignment between the query sequence and the template structure can be
98 found as Supplementary Fig. S6 online.

99 **Building of the complete *HOXB13* model**

100 With the help of the aligned query sequence (NP_006352) and the template structure
101 (2L7Z) data stored in the “hoxb13-2l7z.ali” file, MODELLER v9.17 calculated and predicted the
102 3D model of the complete *HOXB13* protein automatically using its default “automodel” class
103 command. MODELLER v9.17 was instructed to generate 30 similar models of complete
104 *HOXB13* protein based on the 2L7Z template structure and “hox13-2l7z.ali” file. The Python
105 script for the model building was saved as “script4.py”. The complete “script4” s given in the
106 supplementary data.

107 The results of the model building script were stored in the “script4.log” file.
108 MODELLER v9.17 calculated, set the parameters, and computed to build the model
109 automatically. Since we instructed the program to generate 30 similar models, MODELLER
110 v9.17 generated 30 similar models with a “.pdb” file and corresponding log files. The results of
111 the script4 are given in Figure S7. MODELLER v9.17 successfully constructed 30 similar
112 complete *HOXB13* models with their corresponding molpdf values, DOPE score and GA341
113 score, which were helpful in choosing the best model out of the 30 models generated. The entire
114 results of script 4 can be found in Supplementary Fig. S7 online.

115 **Evaluating the generated *HOXB13* models and selecting the best model**

116 There are several criteria to select the best model among the various models generated by
117 MODELLER v9.17. The most important and widely practised criteria includes selecting the
118 model with the lowest DOPE score⁶⁷ and the highest GA341 score⁶⁸. Accordingly, from the
119 summary of the models generated (Figure S7.), we found that the 26th model
120 “hoxb13.B99990026.pdb” had the lowest DOPE score of -10661.23047 and the highest GA341
121 score of 1.00000. Thus, the selected model “hoxb13.B99990026.pdb” was subjected to further
122 validation of protein structure and folding properties with the help of the Ramachandran Plot and
123 PDBSum.

Supplementary Figures

274

275

Figure S1. A graphical representation of the functional domains in the HOXB13 protein. The figure depicts the location of the corresponding domains of HOXB13 with insights into its secondary structure. It consists of two functional domains – Homeobox binding domain and HOXA13 N-terminal domain.

279

280

281 **Figure S2. Steps in Homology Modelling.** The figure depicts the work flow involved in the modelling of
282 complete *HOXB13* protein using MODELLER v9.17

Figure S3. SIFT prediction for the effect of amino acid variations in the non-homeobox region of HOXB13 gene. The figure predicts the effect of amino acid substitution over the entire HOXB13 protein sequence. The above figure corresponds to the SIFT output which is modified and presented only for the amino acids (1-215 and 276-284 AA) corresponding to the non-homeobox region of human HOXB13 gene.

296

297 **Figure S4. Distance tree (BLAST tree view).** The evolutionary distance tree view for the query
 298 sequence NP_006352 of the human HOXB13 gene against the 3D protein structures from PDB by
 299 psiBLAST. The query sequence is highlighted and the structures of 2CRA, 2LD5 and 2L7Z were found
 300 to be closely related to the query sequence. (Figure simulated using psiBLAST)

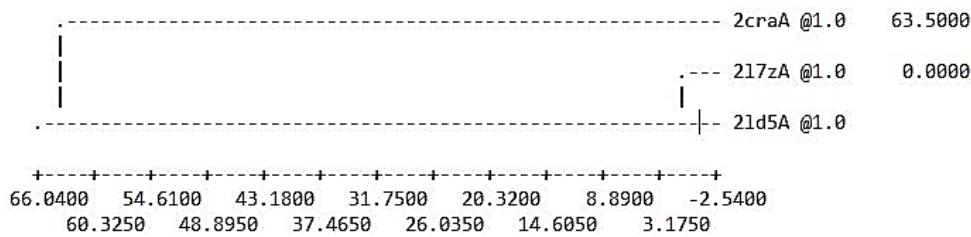

301

Sequence identity comparison (ID_TABLE):

Diagonal ... number of residues;
 Upper triangle ... number of identical residues;
 Lower triangle ... % sequence identity, id/min(length).

2craA @1217zA @121d5A @1			
2craA @1	70	25	25
217zA @1	36	73	67
21d5A @1	37	100	67

Weighted pair-group average clustering based on a distance matrix:

302

303 **Figure S5. Dendrogram of the protein models for template selection.** The dendrogram depicting the
 304 sequence and structural similarity between the query sequence (NP_006352) and the templates (2CRA,
 305 2LD5, 2L7Z) along with the crystallographic resolution and distance score. (MODELLER v9.17 output is
 306 modified and presented only with respect to the dendrogram. The complete log file is given as the
 307 supplementary material).
