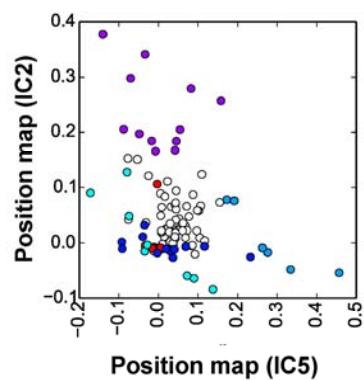

Figure S1. SCA correlation matrix and spectral decomposition for the PtRNase superfamily. a) Positional correlation matrix showing correlations between residues along the primary sequence. b-d) Spectral decomposition of the SCA matrix shows distinct groups of co-evolving residue positions along each independent component (IC). Each circle in the scatter plot corresponds to an amino acid residue represented here using the bovine RNase A primary sequence with amino acids of the different ICs colored as in Figure 1a.

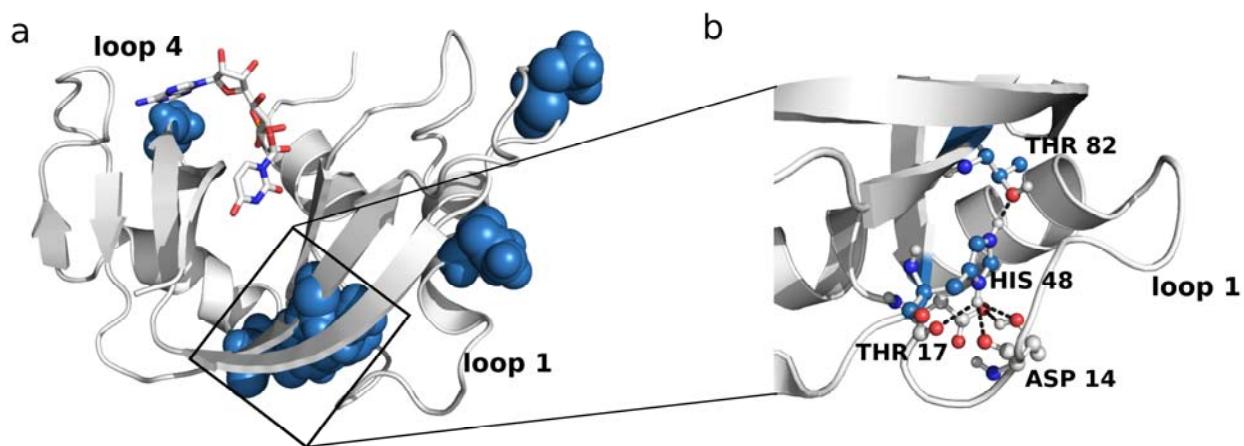

Figure S2. a) Residues of IC5 mapped on the 3D structure of RNase A. b) Zoomed image (of black box in a) of the hydrogen bonding network involving His48 and Thr82 in RNase A. Hydrogen bonds are displayed as dashed lines and atoms of residues presented using the ball and stick model using a standard coloring scheme – blue for nitrogen and red for oxygen. Carbon atoms of residues that are part of IC5 are colored teal while other carbons are colored white. All images were prepared using PyMOL.

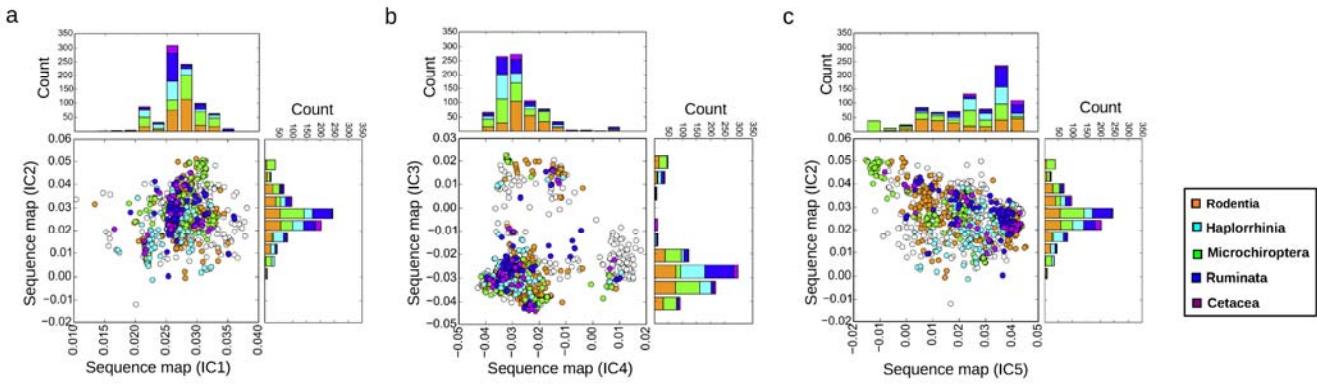

Figure S3. Sequence divergence in the ptRNase superfamily. a-c) Each panel shows the scatterplot of sequences along each IC corresponding to sequence variations of positions contributing to each IC. Stacked histograms show the distribution of sequences along each IC. Sequences are colored based on the taxonomic groups of RNases. Sequence distributions along ICs 1 and 2, 3 and 4, 5 and 2 are shown in panels a, b, and c, respectively.

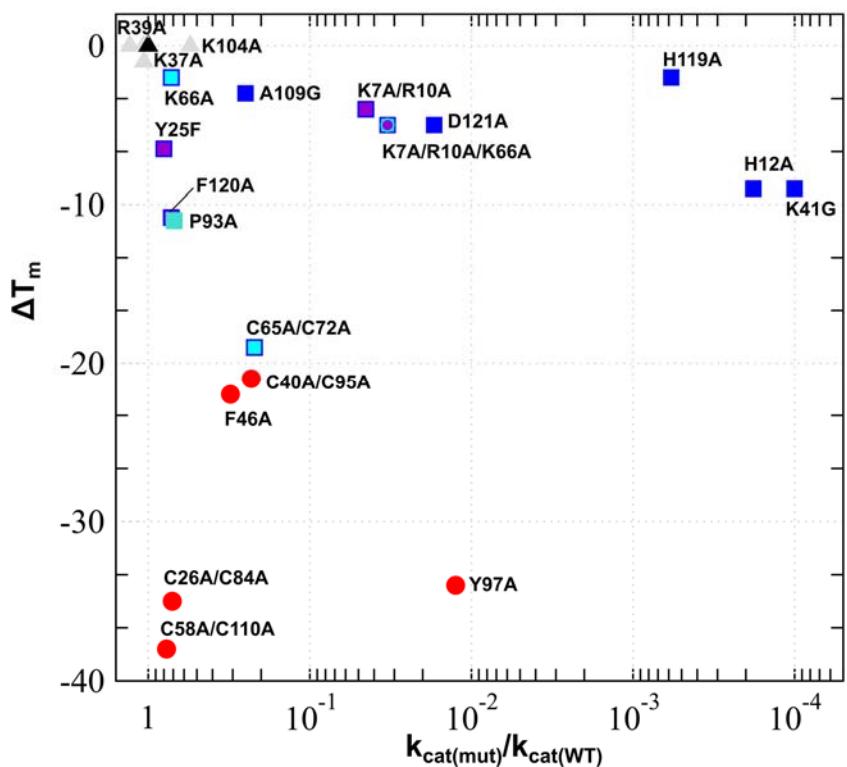

Figure S4. Effects of amino acid mutations in sectors 1 (red circles) and 2 (squares) on the catalytic rate (k_{cat}) relative to wild type and change in thermal stability ($\Delta T_m = T_m(\text{mutant}) - T_m(\text{WT})$) in bovine RNase A. The colors of the squares correspond to the IC subgroups defined in Figure 1. Mutational data were obtained from the literature are presented for all residue positions listed in Table S4. Wild-type data is shown as a black triangle while selected non-sector positions are displayed as grey triangles.
