#### 31 Abstract

#### 32 Background

<u>3</u>3 The number of managed honey bee colonies has considerably decreased in many developed 34 35 35 35 countries in recent years and ectoparasitic mites are considered as major threats to honey bee colonies and health. However, their general biology remains poorly understood.

## **Results**

36 37 We sequenced the genome of Tropilaelaps mercedesae, the prevalent ectoparasitic mite infesting honey bees in Asia and predicted 15,190 protein-coding genes which were well supported by the mite transcriptomes and proteomic data. Although amino acid substitutions have been accelerated within the conserved core genes of two mites, T. mercedesae and Metaseiulus occidentalis, T. *mercedesae* has undergone the least gene family expansion and contraction between the seven arthropods we tested. The number of sensory system genes has been dramatically reduced but T. mercedesae contains all gene sets required to detoxify xenobiotics. T. mercedesae is closely associated with a symbiotic bacterium (*Rickettsiella grylli*-like) and DWV, the most prevalent honey bee virus.

## Conclusions

T. mercedesae has a very specialized life history and habitat as the ectoparasitic mite strictly depends on the honey bee inside a stable colony. Thus, comparison of the genome and transcriptome sequences with those of a tick and free-living mites has revealed the specific features of the genome shaped by interaction with the honey bee and colony environment. Genome and transcriptome sequences of T. mercedesae, as well as Varroa destructor (another globally prevalent ectoparasitic mite of honey bee), not only provide insights into the mite biology, but may also help to develop measures to control the most serious pests of the honey bee.

Keywords: Honey bee decline, Honey bee ectoparasitic mite, Genome, Transcriptome, Proteome, Comparative genomics, Host-Parasite interaction

#### 58 Background

**5**9 The number of managed honey bee (Apis mellifera) colonies has considerably decreased in many 60 developed countries in recent years [1]. Although there are many potential causes for the decline, ₫1 pathogens and parasites of the honey bee, particularly ectoparasitic mites, are considered major Ğ2 threats to honey bee colonies and health [2]. Varroa destructor is present globally and causes 63 abnormal brood development and brood death in honey bees, and is also responsible for the spread of 8 64 honey bee pathogens and parasites [3]. Tropilaelaps mercedesae (small honey bee mite, Fig. 1) is 105 another honey bee ectoparasitic mite which is prevalent in most Asian countries [4]. Thus, these two  $^{11}_{126}$ mite species usually co-exist in a honey bee colony in Asia. Compared to V. destructor, T. 167 mercedesae produces a higher number of offspring and has almost no phoretic period on adult honey  $^{14}_{15}8$ bees, and thus builds up relatively higher population levels within colonies [4, 5]. Similar to V. 169 170 181 272 272 273 274 25 276 destructor, T. mercedesae can vector Deformed Wing Virus (DWV) [6, 7] and influence host immune responses [8]. Furthermore, it has been recently shown that T. mercedesae infestation reduces the longevity and emergence weight of honey bees, and enhances the DWV levels and associated symptoms [9]. The original host of T. mercedesae is the giant Asian honey bee, Apis dorsata, and like V. destructor, it shifted hosts to infest A. mellifera when these colonies were brought into Asia [4]. Although T. mercedesae is currently restricted to Asia, it has the potential to spread and establish all over the world due to the global trade of honey bees. This is exactly what happened with V. destructor [10].

<sup>2</sup>77 28 278 278 T. mercedesae and V. destructor are major threats to the current apiculture industry; however, we do completely understand their sensory development, still not system, sex <sup>3</sup>79 determination/differentiation, reproduction, and the capability to acquire miticide (for example, 31 3**8**0 tau-fluvalinate and flumethrin) resistance. Genomic features of V. destructor were briefly reported 381 before and the associated bacteria and viruses were identified [11]. In this study, we sequenced the <sup>34</sup> 382 genome and transcriptomes of T. mercedesae, supplemented by proteomic data, to provide insights 383 into the above aspects and understand how the mite has evolved under a very specialized <sup>3</sup>87 3884 environment - inside the honey bee colony by depending on the honey bee as the sole host. We will 385 discuss how T. mercedesae may have adapted to its host and environment by shaping its genome.

#### 486 41 487 **Results and Discussion**

## 488 Genome assembly, repeated sequences, and gene annotation

 $^{44}_{489}$ Dual indexed paired-end DNA libraries were prepared from a single adult male and female T. 4**9**0 *mercedesae* for whole-genome sequencing using the Illumina shotgun platform (Supplementary  $^{47}_{481}$ Table 1). The "cleaned" reads from the male mite were then re-assembled into 34,155 scaffolds with 492 an N50 of 28,807 bp representing ~353 Mb of genomic sequence, from which we predicted 15,190 <sup>5</sup>93 51 5**2**4 protein-coding genes (Table 1 and Supplementary Table 2). We found that 95.33% of the "cleaned reads" could be mapped back to this assembly and 244 (98.4%) out of the 248 Conserved Eukaryotic 595 54 596 Genes [12] as well as 83% of 2,675 arthropod BUSCOs [13] were annotated from the assembled genome (Supplementary Table 3). These are comparable to those reported for nine other arachnids 5**9**7 (Table 1 and Supplementary Table 3). Proteomic characterization of the adult males and females <sup>5</sup>788 yielded 124,798 mass spectra in total and 60,463 were assigned to the peptides of annotated proteins 5**9**9 above (Supplementary file 1). With k-mer statistics [14], the size of the T. mercedesae genome was

- 60
- 61 62

100 estimated to be 660 Mb with a peak k-mer depth of ~60X, and thus approximately 50% of the 1¢1 genome DNA was inferred to comprise repetitive sequences (Supplementary Fig. 1). Repetitive 102 sequences such as DNA transposons, retrotransposons including LINE (Long Interspersed Nuclear 1**₫**3 Element), SINE (Short Interspersed Nuclear Element), and LTR (Long Terminal Repeat) as well as 104 satellite DNA represent only 7 % of the assembly. But they occupied 48.57% of total clean reads 105 (Supplementary Table 4) and the majority of them were found in the high-coverage regions of the 1**Q**6 genome (Supplementary Table 5), suggesting that repetitive sequences have been collapsed in the 107 genome assembly. We thus concluded that the qualities of draft genome sequence and protein-coding 108 gene set were sufficiently robust for further characterization of T. mercedesae genome and 109 transcriptome.

**1‡**0 Flow cytometric measurement of T. mercedesae nuclear DNA content together with the k-mer 111 statistics demonstrated that the male mite assumed to be haploid with ~660 Mb (1C) DNA. The 112 female mite was twice that size and assumed to be diploid at 1,287 Mb (2C) DNA (Supplementary 1<u>3</u>3 Fig. 2). Thus, T. mercedesae may use haplodiploidy for sex determination, and the genome size of T. ₽₽4 *mercedesae* is the largest among those of mites whose genomes have been sequenced (V. destructor, <u>j</u> Metaseiulus occidentalis, Tetranychus urticae, Sarcoptes scabiei, and Dermatophagoides farinae) **₽**₽6 [15-17, 11, 18] but smaller than those of ticks (for example, *Ixodes scapularis* [19]). As expected **β‡**7 from the largest genome size among the sequenced mites, gene density is low in the T. mercedesae 218 genome (with larger intergenic regions); reminiscent of the large velvet spider (Stegodyphus  $\frac{279}{28}$ mimosarum) and the black-legged tick (I. scapularis) genomes (Supplementary Fig. 3). Although the 1<u>2</u>30 exon size range was comparable in all tested genomes (small honey bee mite, predatory mite, **Å2**1 black-legged tick, velvet spider, spider mite, fruit fly, and honey bee) (Supplementary Fig. 4A), the 31 1<u>3</u>22 average size of introns in T. mercedesae is larger than that in two other mites and insects that were 123 123 124 analyzed (Supplementary Fig. 4B). We also successfully annotated genes encoding rRNA, tRNA, snRNA, and miRNA in the *T. mercedesae* genome (Supplementary Table 6), obtained RNA-seq data **B2**5 from T. mercedesae adult males and females as well as nymphs, and assembled the reads to aid <u>1</u>276 protein-coding gene annotation and to compare their gene expression profiles.

#### **b2**7 **Comparative genomics**

**†**28 The protein-coding genes of T. mercedesae were compared with those of six other arthropods  $\frac{4}{129}$ (mentioned above) and a nematode. Phylogenetic trees constructed using 926 highly conserved 1:1 **‡**30 orthologs implementing both maximum likelihood and Bayesian methods demonstrated that the  $\frac{44}{431}$ Tropilaelaps mite and the predatory mite cluster together; however, the spider mite forms an **#3**2 outgroup to two other mites, the black-legged tick, and the velvet spider (Fig. 2A). This is consistent <sup>4</sup>333 with previous reports that the subclass Acari is diphyletic, with the superorders Acariformes (spider **1**34 mite) and Parasitiformes (Tropilaelaps mite and predatory mite) being distantly related [20, 21]. **‡**35 Since above three mite species have similar body structure and morphology, this could be an <u>1</u><u>3</u>6 example of convergent evolution [22]. The molecular species phylogenetic tree also indicates the **∲**37 variable evolutionary rates in gene sequence; with the branch of T. mercedesae and M. occidentalis 54 138 exhibiting the fastest rate among arthropods we tested (Fig. 2A).

OrthoMCL classified the predicted proteins of *T. mercedesae* together with proteins from six other arthropods and outgroup into a total of 15,506 orthology clusters. As expected from the phylogenetic tree, the *Tropilaelaps* mite shares the most orthology clusters (1,215) with the

4

61

142 predatory mite (Fig. 2B). Among these orthology clusters, GO terms related with 'Structural 143 constituent of cuticle', 'Regulation of DNA methylation', and 'Xenobiotic metabolic process' are 144 enriched (Supplementary Table 7). We found 119 orthology clusters consisting of 332 1**4**5 species-specific genes and 5,846 unclustered genes which were not classified to any orthology 146 clusters by orthoMCL are only present in T. mercedesae but not in the other reference genomes 147 analyzed (Fig. 2A and B). These unclustered genes may include both T. mercedesae-unique genes 148 and paralogs which have extensively diverged from their orthologs so that their sequence similarity 149 was not detected by orthoMCL. We found that 1,981 unclustered genes could be assigned with at 150 least one GO term and among these lineage-specific genes, three GO terms, 'Structural constituent of 151 cuticle', 'Nucleosome', and 'DNA bending complex' are highly enriched (FDR  $< 1.50 \text{ E}^{-04}$ ) 152 (Supplementary Table 8). T. mercedesae contains 117 members of the cuticle protein family [23], in 153 which 53 are novel among the seven arthropods analyzed, suggesting that the mite's exoskeleton has 154 18 155 rapidly evolved. Two other enriched GO terms could be involved in the epigenetic control of gene expression. Among 226 orthology clusters that are shared between T. mercedesae, M. occidentalis, **£9**6 and I. scapularis, GO terms related with 'Transporter activity' are highly enriched. We found that 135 21 1577 orthology clusters specifically shared between T. mercedesae and I. scapularis were enriched with 258 GO terms related to 'Renal tubule development', perhaps to maintain a constant water level following  $\frac{1}{25}$ 9 the intake of a large volume of hemolymph or blood, respectively [24, 25] (Supplementary Table 9).

260 We used CAFE to infer gene family expansion and contraction in T. mercedesae together with <u>f</u>g1 six other arthropod species. We found that T. mercedesae has undergone the fewest gene family <u>1</u>62 expansion/contraction events since divergence from the common ancestor of arthropods **P**03 (Supplementary Fig. 5). This feature may fit to the specific life history of a mite parasitizing only the 164honey bee and living inside a colony with an enclosed, stable environment. However, there are some **B**65 significantly expanded gene families (P-value < 0.001) associated with zinc ion binding and peptide 34 166 cross-linking. Meanwhile, one of the HSP70 gene families (Heat shock 70 kDa protein cognate 4) **B6**7 has significantly contracted in T. mercedesae (Supplementary Table 10), perhaps because the mite **1**68 spends most of its time in the honey bee brood cell where the temperature is constantly around 35°C 369 [26]. We analyzed 91 genes with  $d_N/d_S > 1.0$  in *T. mercedesae* using the one ratio model (null model) 1470 to test the significance, and found that four genes have evolved rapidly either due to relaxation or 41 14721 positive selection (Supplementary Table 11). Among them, Tm 07523 encodes an **1**72 endo- $\beta$ -N-acetylglucosaminidase-like protein, a chitinase, which could be involved in processing 44 1473 chitin specifically present in T. mercedesae.

#### **174** Sensory systems

 $\frac{47}{485}$  *T. mercedesae* has a very specific life history and habitat as a honey bee ectoparasitic mite. The mite depends only on the honey bee as the host and spends most of its life in the capped brood cell. Thus, they are likely to depend on the chemosensory rather than the visual system to seek out the fifth instar honey bee larva and the mating pair. Therefore, we annotated and analyzed genes associated with phototransduction and chemosensory systems in *T. mercedesae*.

We found that the homologs of *D. melanogaster* opsins, arrestin, TRPL, and INAD are absent in 1581 *T. mercedesae* (Supplementary Fig. 6). Since they are the major components for fruit fly photoreception, *T. mercedesae* appears to be blind, and this is consistent with the lack of eye structures. Nevertheless, the adult females immediately move out from a brood cell when the cap is 157

5

61

184 removed and exposed to light, suggesting that they may be able to respond to light. T. mercedesae 185 has two *peropsin* genes, as do predatory mites [21] (Supplementary Fig. 7). Peropsin is a retinal 186 photoisomerase that converts all-trans-retinal to 11-cis-retinal and may couple with a G-protein 1**§**7 through the conserved 'NPXXY' motif at the seventh transmembrane domain [27]. The existence of 188 this gene in the jumping spider, black-legged tick, and humans suggests that peropsin may have been 189 lost specifically in insects. However, its function in vision or other pathways remains to be 1<u>§</u>0 determined. Only one of two peropsin genes (Tm\_08036) appears to be expressed in the T. 191 mercedesae transcriptome, and it was highly expressed in the female compared to the male 192 (Supplementary Fig. 8). Female may use this peropsin to move out from the brood cell for 193 reproduction. The other components in phototransduction are present in T. mercedesae, suggesting 194 that they could be involved in other signaling pathways. In contrast to T. mercedesae, M. 195 occidentalis was reported to contain more molecular components for light perception such as 196 arrestins and INAD and exhibit genuine light-induced behaviors in the absence of eyes [21]. 1<u>9</u>7 Meanwhile, I. scapularis contains seven opsins, including orthologs of the insect long-wavelength **£9**8 sensitive visual opsins [28], demonstrating that the tick uses more visual cues for location of mates, 1299 hosts and oviposition sites than the mites above.

200 Insect gustatory receptors (GRs) are multifunctional proteins for the perception of taste, airborne **2**Ø1 molecules, and heat [29]; however, their functions in other arthropods have not been addressed. We 202 found only five GRs in T. mercedesae (TmGRs) and their orthologs are absent in D. melanogaster  $\frac{2}{2}\frac{1}{8}$ (Fig. 3). I. scapularis has expanded the specific group of GRs [28], and five TmGRs cluster with the 204 tick's GRs, suggesting that these are expansions specific to Acari. Because they share a common 205 ancestor with the *D. melanogaster* sugar receptor, they could be involved in taste perception (Fig. 3). 206 Among the five TmGRs, one gene (Tm\_15249) is likely to be a pseudogene due to internal stop 207 codons in the open reading frame. Expression of only two TmGR genes (Tm\_03548 and Tm\_09509) 348 2018 was supported by RNA-seq data. Tm\_09509 mRNA is highly expressed in adult females and 209 Tm 03548 mRNA is only detected in males at low levels (Supplementary Fig. 9), suggesting that Ž70 they may respond to different ligands.

**21** Ionotropic receptors (IRs) belong to a large family of ligand-gated ion channels, which also 212 41 2123 include ionotropic glutamate receptors (iGluRs) with the major roles in synaptic transmission. IRs appear to represent protostome-specific ancient olfactory and gustatory receptors [30]. We annotated **2**4 eight IR and 34 iGluR genes in the T. mercedesae genome. In the eight annotated T. mercedesae IR  $\frac{44}{245}$ (TmIR) genes, Tm\_15231 and Tm\_15229 are orthologs of DmIR25a and DmIR93a, respectively 2₽€6 (Supplementary Fig. 10), which are expressed in the olfactory sensory neurons of D. melanogaster 2477 antennae [31]. Furthermore, DmIR25a has been recently shown to be involved in fruit fly **21**8 temperature sensation [32, 33]. The results of qRT-PCR revealed that these two genes are highly Ź19 expressed in the first legs of T. mercedesae (Supplementary Fig. 11), which function as the major ž20 sensory organs similar to insect antennae [34]. Thus, these two TmIRs may represent the ancient **Ź**Ź1 receptors present in the common ancestor of arthropods. It appears that six other TmIRs have arisen 2<u>2</u>22 specifically in a mite lineage (Supplementary Fig. 12).

Interestingly, there are no OR (olfactory receptor), OBP (odorant binding protein), and CSP  $\frac{57}{284}$  (chemosensory protein) genes in the *T. mercedesae* genome (Table 2). Since OR and OBP genes are also absent in *M. occidentalis*, the black-legged tick, the centipede (*Strigamia maritima*), and the

6

61

226 water flea (Daphnia pulex), these appear to have evolved specifically in insect genomes as 227 previously suggested [35]. Nevertheless, CSP genes must be ancient and may have been specifically 228 lost in the two mite species. Despite of the potential importance of chemical communication for the 2**2**9 life cycle [4], T. mercedesae has only four functional GRs and eight IRs, but no OR, OBP, or CSP 230 genes. The presence of few orthologs between T. mercedesae and D. melanogaster suggests that the 231 last common ancestor of arthropods had very few GRs and IRs. These chemoreceptors appear to 232 have expanded in arthropod species in a lineage-specific manner [36]. In fact, Parasitiformes 233 exposed to more variable environments, i.e., M. occidentalis and I. scapularis, have more GR and IR 234 genes than the more strictly host-dependent T. mercedesae (Table 2). Simplified behavioral patterns 235 under a dark and stable environment inside a honey bee colony and capped brood cell may have 236 reduced the number of tools in the sensory system in T. mercedesae.

### **237** Detoxification system

238 Three major groups of enzymes have important roles for metabolizing toxic xenobiotics in insects <u>4</u><u>3</u>9 and the acquisition of insecticide resistance; cytochrome P450s (P450s), glutathione-S-transferases 240 (GSTs), and carboxylesterases (CCEs) [37]. P450s and CCEs are also involved in the synthesis and 241 241 degradation of ecdysteroids, juvenile hormones, pheromones, and neurotransmitters [38, 39]. 2442 After the actions of P450s and CCEs followed by GSTs, the xenobiotics-derived polar compounds or  $\frac{24}{25}3$ conjugates can be transported out of the cell by ATP-binding cassette transporters (ABC transporters) **244** [40]. In some cases, ABC transporters and others directly and efficiently transport xenobiotics out of  $\frac{2}{28}$ the cell without enzymatic modifications to prevent the exertion of toxicity [40]. Since various **24**6 natural and synthetic chemical compounds have been used to control honey bee mites, it is of 247 considerable interest to understand how T. mercedesae may detoxify such miticides and develop 348 2342 8 resistance.

249 We manually annotated 56 T. mercedesae P450 (TmP450) genes in which 18 appeared to be 34 2350 pseudogenes. In fact, the expression of none of these genes was supported by RNA-seq data. Thus, T. 251 mercedesae has only 38 apparently functional P450 genes similar to the human louse, Pediculus zzz humanus [41], and the expression of 36 genes were confirmed by RNA-seq data (Supplementary 253 Table 12). Similar to insect P450s, they are phylogenetically clustered into CYP2, CYP3, CYP4, and 2594 41 2455 mitochondrial clans (Fig. 4). The classification was based on D. melanogaster P450s, but only three TmP450 genes (Tm11277, Tm11316, and Tm10252) have D. melanogaster P450 (DmP450) 2496 44 2457 orthologs classified as CYP2 and mitochondrial clans (Fig. 4 and Table 3). Thus, only a few P450 genes were present in the last common ancestor of arthropods and might be associated with the 2458 synthesis and degradation of hormones. In the two large CYP3 and CYP4 clans, DmP450s and the 2459 mite P450s are phylogenetically separated, suggesting that they have independently expanded after 260 the split of the ancestors of mites and insects (Fig. 4). All of the TmP450 genes have orthologs in the **2**81 M. occidentalis genome as recently reported [42], but M. occidentalis has 12 and 13 more genes than ž<u>6</u>2 T. mercedesae in the CYP2 and CYP3 clans, respectively, by our analysis (Table 3). T. mercedesae 263 appears to have lost the CYP3 clan members from the common ancestor of the Parasitiformes (Fig. 54 **26**4 4) as suggested by CAFE analysis (Supplementary Table 13). Some of the TmP450 genes are 265 differentially expressed between nymph, adult male, and adult female (Supplementary Fig. 12 and  $\frac{57}{266}$ Supplementary Table 14), suggesting that they would be involved in the synthesis and degradation of 207 hormones to control molting and sex-specific specific phenotypes of T. mercedesae.

- 60 61
- 62
- 63
- 64 65

268 T. mercedesae has 15 GST genes (TmGST) in which eight appear to be pseudogenes without 2¢9 evidences of the mRNA expression in the transcriptomes. This leads to only seven functional 2720 TmGST genes with mRNA expression confirmed by RNA-seq data (Supplementary Table 15). 271 According to the reference data sets (D. melanogaster and T. urticae GSTs), the phylogenetic 272 analysis of TmGSTs revealed the presence of four subfamilies (delta, mu, omega, and kappa), and an 273 unclassified TmGST gene (Supplementary Fig. 13). Members in the mu, delta, epsilon, omega, theta, 234 and zeta GST subclasses have been reported to function in a wide range of detoxification [43]. 275 Epsilon, sigma, theta, and zeta subfamilies are absent in both T. mercedesae and M. occidentalis by 276 our analysis in contrast to the recent report [42]; however, I. scapularis contains epsilon and zeta 277 subfamilies and *T. urticae* has the theta subfamily (Supplementary Table 16). This suggests that these 2<u>7</u>8 three subfamilies have been lost from the T. mercedesae and M. occidentalis genomes. The full 279 length orthologs of the five TmGST pseudogenes (Tm\_05455, Tm\_09167, Tm\_15202, Tm\_15203, 280 and Tm\_15206) are present in *M. occidentalis* (Supplementary Fig. 13), suggesting that the delta and **28**1 mu GST subfamilies have undergone constriction in T. mercedesae.

282 Insect CCEs can be divided into 14 subfamilies (A to N) with three major groups based on the  $\frac{21}{28}$ 3 functions of dietary detoxification (A-C), hormone and pheromone degradation (D-H), and 284 neurotransmitter degradation (I-N) [44]. We manually annotated 50 T. mercedesae CCE genes, in 285 286 286 which eight appeared to be pseudogenes without mRNA expression (Supplementary Table 17). The number of functional CCE genes in T. mercedesae is thus comparable to that in M. occidentalis [42]  $\frac{228}{28}$ (Supplementary Table 18). Intriguingly, there are no mite CCEs in the subfamilies AF, H, I, K, and 288 N; however, a massive mite specific expansion is found in the subfamilies J and M by our analysis 289 (Supplementary Fig. 14 and Supplementary Table 18). Only three TmCCE genes (Tm 00126,  $31 \\ 39 \\ 29 \\ 20$ Tm\_05721, and Tm\_08305) have D. melanogaster orthologs, suggesting that CCE genes have 291 independently duplicated in insects and mites. The expression of some TmCCE genes is biased zg22 between the nymph, adult female, and adult male (Supplementary Table 19). Above results 293 demonstrate that T. mercedesae contains P450s, GSTs, and CCEs although the number and Ž384 composition of subfamilies are different from those of other arthropods. Some of these enzymes may 295 engage in detoxifying miticides and other xenobiotics in T. mercedesae.

296 41 297 We annotated 54 ABC transporter genes in the T. mercedesae genome, and the expression of 47 genes was confirmed by RNA-seq data (Supplementary Table 20). Similarly, M. occidentalis **2**98 contains 57 ABC transporters that are comparable to those present in *D. melanogaster* (56 genes) <sup>4</sup>/<sub>4</sub> <sup>4</sup>/<sub>5</sub>9 (Supplementary Table 20). However, mite-specific expansion is found in the ABCC subfamily, and **3**00 instead fruit fly-specific expansion is observed in the ABCG subfamily (Supplementary Fig. 15). The **3**₫ ABCC subfamily includes many vertebrate multidrug-resistance associated proteins (MRPs) that 302 extrude drugs with broad specificity [40]; thus, the expanded ABCC subfamily members in T. **₹**Ø3 mercedesae could be involved in conferring resistance against various miticides. In the fruit fly, 304 expansion has been observed of the ABCG subfamily, which contains the transporters for the uptake <del>3</del>065 of pigment precursors into the cells of the Malpighian tubules and developing compound eyes 306 (Supplementary Fig. 15). Because these mites do not have eyes, fewer numbers of the ABCG 307 transporters would be sufficient. The mites and fruit fly appear to have independently expanded ABCA subfamily members (Supplementary Fig. 15). These results suggest that most of the ABCA 309 and ABCC transporters may carry out different functions in mites and fruit flies. Interestingly, two

8

- 60
- 61 62

transporters, Tm\_07059 and Tm\_14842, form an independent clade separated from eight previously known ABC transporter subfamilies. In cases where the mite ABC transporter genes show biased expression between female, male, and nymph, most of them are highly expressed in either male or nymph compared to female (Supplementary Table 21).

#### 314 Sex determination genes in *T. mercedesae*

31/5 Arthropods are known to use various strategies for sex determination [45]. In contrast to T. 316 mercedesae, which is likely to use haplodiploidy, M. occidentalis employs parahaploidy, in which the **3**17 functional elimination of paternal chromosomes occurs during early embryogenesis resulting in male 318 development [46, 21]. To gain insight into the mechanism of sex determination of T. mercedesae, we 3139 manually annotated the candidate genes for sex determination in the T. mercedesae genome. \$**2**0 Similarly to M. occidentalis [21], T. mercedesae does not contain upstream sex determination genes 321 (Sex-lethal and transformer) but has the homologs of downstream sex determination genes, 3<u>7</u>22 transformer-2, dmrt (doublesex and mab3 related transcription factor), and intersex. T. mercedesae <u>3</u><u>3</u>3 has the most *dmrt* genes of the arthropods that we tested (Supplementary Table 22) and has two extra 324 dsx genes compared to M. occidentalis (Supplementary Fig. 16). The Dmrt93B ortholog is present in <u>3</u>25 T. mercedesae (Tm\_07872) but not in M. occidentalis (Supplementary Fig. 16), and all of the dmrt 326 genes are highly expressed in the male (Supplementary Fig. 17). These results suggest that T. 327 3257 mercedesae and M. occidentalis may use a different set of genes for sex determination.

**328** Comparison of gene expression profiles between nymphs and adult males and females

 $\frac{2}{28}$ Comparison between adult male and female transcriptomes and proteomes revealed that <u>3</u>30 histone-lysine-N-methyltransferase gene family and N-acetyltransferase gcn5 gene family were 331 highly expressed in the male compared to the female (Fig. 5, Supplementary file 1, and <sup>31</sup> 3322 Supplementary Table 23), suggesting that the male mite may mostly depend on histone modifications **33**3 for the epigenetic control of gene expression. This could be due to the ploidy compensation between 3<u>3</u>4 3<u>3</u>34 males with haploid genomes and females with diploid genomes. At the protein level, males displayed 335 overrepresentation of 26S proteasome subunits and a 17-beta-hydroxysteroid dehydrogenase (Fig. 5), 336 which accords with the importance of the ubiquitin-proteasome system in sperm maturation [47] and 337 a potential role for ecdysteriods in sexual maturation of *T. mercedesae* [48]. The female mite highly 338 expresses the vitellogenin gene family and cathepsin L-like proteases (Fig. 5 and Supplementary 339 Table 23). This is consistent with active oogenesis in female mites, since both vitellogenin protein **3**40 and Nanos mRNA would be deposited in the oocyte; while cathepsin L proteases may have a critical  $\frac{44}{34}$ role in volk processing as in C. elegans [49]. The results of above transcriptome and proteome **3**42 analyses are not identical but a concordant set of 74 and 13 genes are up-regulated in the male and <u></u> females, respectively. Comparison between adult female and nymph transcriptomes demonstrated **34**4 that 46 out of the 125 cuticle protein gene families, 13 out of 24 chitin binding domain-containing **3**45 protein gene families, and nine out of 16 chitinase gene families are expressed at a higher level in  $3\bar{4}6$ nymphs than in adult females (Supplementary Table 24), indicating that chitin metabolism as well as **3**¥7 exoskeleton formation by molting is stimulated in the nymph. The nymph also highly expresses 18 348 348 out of 29 protocadherin/fat gene families and 18 out of 44 epidermal growth factor-related receptor 349 gene families. These are likely to be involved in cell-cell adhesion and cell proliferation associated 357 350 with the increase of cell number in nymph. Consistent with above results, GO analysis of genes 391 highly expressed in nymphs compared to the adult females demonstrated that many GO terms related

60

61

62 63

63 64

to cuticle formation and appendage morphogenesis are enriched (Supplementary Table 25).

# 353 Symbiotic bacteria and infecting virus

354 Several bacteria have been shown to associate with mites and ticks [17, 50, 51]; however, bacteria 3<u></u>∮5 associated with honey bee mites have not yet been fully investigated [11]. We thus attempted to 356 identify any bacteria associated with T. mercedesae by filtering the bacteria-derived DNA contigs 357 during the mite genome assembly. In the male and female GC%-coverage plots, some contigs were 358 initially annotated as bacterial DNA in the major blue blob, and most of these were identified to 359 contain Wolbachia sequences by BLASTN searches (Fig. 6). We confirmed that parts of Wolbachia 360 genes are integrated into the mite genome by testing two genomic contigs using PCR with two sets 361 of primers (one primer located in the mite gene, and the other in the Wolbachia gene) 3¢2 (Supplementary Fig. 18A and B). This phenomenon of nuclear Wolbachia transfers, or nuwts, has 363 been observed widely in other arthropods and in nematodes [52], although to the best of our <u>3</u>64 knowledge, this is the first report for a chelicerate. It suggests that T. mercedesae or the ancestor had <u>3</u>65 Wolbachia as the endosymbiont in the past. Meanwhile, we extracted all reads mapped to the red 306 blob (bacterial origin) in the female plot (Fig. 6) and re-assembled them into 96 contigs. We 367 annotated 751 protein-coding genes from the 81 contigs and found that 667 of these show high 368 similarity to those of *Rickettsiella grylli* with an average identity of 79%. The rest of the 84 369 protein-coding genes showed similarity to 20 other bacteria species, such as Diplorickettsia 370 massiliensis and Legionella longbeachae. This demonstrates that a close relative of R. grylli  $\frac{27}{28}$ associates with female but not male T. mercedesae. Rickettsiella is an intracellular <u>3</u>72 gamma-proteobacterium associated with a wide range of different arthropods without major 373 pathogenicity to the host [53]. Wolbachia endosymbiont in the past may have been replaced by a 31 3724 species related to R. grylli in T. mercedesae. The potential effects on T. mercedesae as well as the 375 potential for transmission to the honey bee remain to be determined. Since we did not find any DNA 3<u>3</u>46 sequences of actinomycete species in our sequence reads, the two major ectoparasitic mites of honey 3767 bee (V. destructor and T. mercedesae) do not appear to share the same bacteria [11]. Nevertheless, 378 both mites do not contain common arthropod gut bacteria, suggesting that they are not essential for 379 the honey bee mites.

3<u>48</u>0 We also assembled DWV RNA in the adult male and female, as well as nymph, transcriptomes 381 (Supplementary Table 26). This is consistent with previous reports [54, 6, 7]; however, our data **3**<del>8</del>2 expand the infected stages to include the adult males and nymphs. DWV sequence reads represented <sup>44</sup> 383 one third of the whole RNA-seq data, and these very high levels of DWV RNA were further **3**84 confirmed by qRT-PCR (Supplementary Table 27). The proteomic analysis of females and males <u>\$</u>85 recovered many peptides derived from the capsid (structural) proteins, but very few peptides from 386 the non-structural proteins of DWV, demonstrating that the majority of DWV associated with the 387 mites exists as mature virions (Supplementary Fig. 19). Similar observations were also reported for V. 388 destructor [55]. We assembled three full length DWV RNA genomes and found that they are <del>3</del>89 phylogenetically clustered with type A DWV [56] (Fig. 7). Thus, T. mercedesae may spread the 390 specific strain of DWV (type A in this study) to honey bees as suggested for V. destructor [57]. **39**1 Considering that T. mercedesae was unlikely to carry DWV when associated with the original host, <u>z</u><u></u>22 A. dorsata, DWV infection could impose a negative impact on the mite. It will be crucial to 393 understand the nature of interactions between honey bee, mite, and DWV to measure the impact of T.

10

60 61

62

63

mercedesae infestation on honey bee colonies. However, in contrast to *V. destructor*, we did not detect baculoviruses in either the genome and transcriptome sequences [11].

### 396

# 3<sup>4</sup>/<sub>2</sub>7 Conclusions

- $3\vec{9}8$  *T. mercedesae* has a very specialized life history and habitat as an ectoparasitic mite strictly depending on honey bees in a colony with closed and stable environment. Thus, comparison of the genome and transcriptome sequences with those of a free-living mite and a tick has revealed the specific features of the genome shaped by interaction with the honey bee and colony environment.
- $\frac{40}{22}$  Our key findings are the followings;
- **403** 1) Amino acid substitutions have been accelerated within the conserved core genes of *T. mercedesae* and *M. occidentalis*
- 405 2) *T. mercedesae* has undergone the least gene family expansion and contraction between the seven 406 arthropods we tested
- $\frac{1}{407}$  3) The numbers of HSP70 family genes and sensory system genes are reduced
- 408 4) *T. mercedesae* may have evolved a specialized cuticle and water homeostasis mechanisms, as well
  409 as epigenetic control of gene expression for ploidy compensation between male and female
- 430 5) *T. mercedesae* contains all gene sets required to detoxify xenobiotics, enabling it to be miticide  $\frac{24}{251}$  resistant
- **41** 6) *T. mercedesae* is closely associated with a symbiotic bacterium (*Rickettsiella grylli*-like) and **41** 3 DWV, the most prevalent honey bee virus.
- **444**

Manipulation of symbiotic *R. grylli*-like bacteria in the female mites may give the opportunity to control *T. mercedesae* in the future. Our *T. mercedesae* datasets, alongside published *V. destructor* genome and transcriptome sequences, not only provide insights into mite biology, but may also help to develop measures to control the most serious pests of the honey bee. 419

# **43 Methods**

## **421** Mite sample collection

Based on the morphological and ethological characteristics [58], adult males and females as well as nymphs of *T. mercedesae* were identified and collected from a single honey bee colony for the flow cytometric analysis and Illumina sequencing (genome and transcriptome). Meanwhile, the adult females #2 sample (Supplementary Table 1) was collected from a different colony. Both colonies were obtained from a beekeeper in Jiangsu Province, China. The mites collected for genome for genome for RNA-seq were sorted at -80°C before the transport.

# **4**29 Genome sequencing

Before DNA extraction, the mite bodies were carefully washed twice with acetone to remove any non-target organisms that might adhere on the mite surface. Subsequently, a single male and a single female mite were air dried (15 min) and individually triturated in 180  $\mu$ L of lysozyme buffer (1M Tris-HCl, 0.5M EDTA, 1.2% Triton X-100, and 0.02% lysozyme) with a tissuelyser II (Qiagen, Valencia, USA) using a 3 mm stainless steel bead at 25,000 motions/min for 30 sec. After incubating the samples at 37 °C for 30 min, total DNA was extracted from each of the triturated samples with

- 60 61
- 62

436 DNeasy Blood and Tissue kit (Qiagen) by following the manufacturer's spin-column protocol for 437 animal tissue. To maximize the yield of DNA extraction, two successive elution steps, each with 50 438 µl elution buffer, were performed. The DNA concentrations were determined by spectrophotometry, 4<u></u>\$9 a sensitive and commonly used fluorescent dye assay (Qubit® dsdna BR assay, Life Technologies 440 Europe, Naerum, Denmark) according to the manufacturer's instructions. Two paired-end Illumina 441 DNA libraries were constructed with the male and female total genomic DNA samples (30 ng each) 442 using a Nextera DNA sample preparation kit (Illumina, Great Chesterford, United Kingdom). The 443 DNA libraries were then quality controlled and sequenced with Illumina Hiseq 2500 system using 444 two individual lanes in the Centre for Genomic Research at the University of Liverpool. The raw 445 fastq files were trimmed to remove Illumina adapter sequences using Cutadapt (v1.2.1) [59]. The 446 option "-O 3" was set, so the 3' end of any reads which matched the adapter sequence over at least 3 447 bp was trimmed off. The reads were further trimmed to remove low quality bases, using Sickle 448 18 449 (v1.200) [60] with a minimum window quality score of 20. After trimming, reads shorter than 10 bp were removed.

# **490** Transcriptome sequencing

 $\frac{21}{451}$ Male, female and nymph mites were shipped to BGI-Shenzhen with dry ice for total RNA extraction, **4**52 polyA<sup>+</sup> RNA enrichment, cDNA library preparation, and Illumina Hiseq 2000/4000 sequencing. 4253 42554 Total RNA (Supplementary Table 1) was extracted from a pool of 20~30 mites using Trizol reagent (Qiagen) and treated with DNase I (Qiagen). Next, polyA<sup>+</sup>RNA was isolated by magnetic beads with  $\frac{2}{28}$ oligo (dT) and digested to short fragments by mixing with the fragmentation buffer, and then the **45**6 cDNA was synthesized. The short DNA fragments were purified and resolved with EB buffer for **₽**97 end reparation and single nucleotide A (adenine) addition followed by ligation with adapters. DNA  $\frac{3}{452}8$ fragments suitable for sequencing were then selected for the PCR amplification. After QC steps, 459 Illumina Hiseq 2000 system was used to sequence the libraries of adult males #1 (in two lanes), adult 34 4<u>6</u>0 females #1 (in two lanes), nymphs #1 (in two lanes) and adult females #2 (in a single lane), whereas **46**1 adult males #2 and nymphs #2 were sequenced with Illumina Hiseq 4000 system in a single lane. 462 Raw reads were trimmed and filtered by internal tools of BGI-Shenzhen.

### 463 Estimation of genome size and ploidy of *T. mercedesae*

**4**84 Nuclear DNA contents of T. mercedesae males and females were estimated by a method of  $4_{465}^{41}$ propidium iodide staining followed by flow cytometry [19]. Nuclei were isolated from ten T. **4**66 *mercedesae* adult males and females, the heads of ten *D. melanogaster* females (1C = 175Mb) [61]  $44_{46}^{4}$ 7 and the brain of a honey bee worker (1C = 262 Mb) [62] by homogenizing each sample with 1 mL of **46**8 a cold Galbraith buffer (30 mM sodium citrate, 18 mM MOPS (3-morpholinopropanesulfonic acid), 469 21 mM MgCl<sub>2</sub>, 0.1% Triton X-100, 1 mg/L RNase A) using a loose pestle. The cellular debris were 40 removed by filtering through 20 µm nylon mesh. Stained nuclei from adult male and female mites ₹71 were independently analyzed with two reference standards using a BD FACS flow cytometer (BD **4**<u>7</u>2 Biosciences, San Jose, CA). Nuclear genome size was then calculated according to the following ₽73 formula: Sample nuclear DNA content = (Mean peak of sample/Mean peak of reference standard)  $\times$ 54 **4**74 nuclear DNA content of reference standard. We estimated the genome size by analyzing the **4**775 frequency of k-mers counted by Jellyfish [63] with the following formula [64]: Estimated genome 57 4586 size (bp) = total number of k-mer/the maximal frequency. The ploidy is the ratio of nuclear DNA **4**77 content to genome size.

- 60
- 61 62

#### 478 *De novo* assembly of genomic DNA

 $4\frac{1}{2}9$ Prior to assembly, we discarded all male and female sequencing reads aligned to honey bee genome 480 sequence by Bowtie 2 (v2.2.1) [65]. The unaligned male and female reads were then extracted by 4**₫**1 bam2fastq (v1.1.0) and assembled individually by Velvet v1.2.07 [66] into preliminary contigs with 482 their best k-mers and parameters of '-min\_contig\_lgth=200 and -ins\_length 1105 (male)/939 483 (female)'. DNA sequences derived from non-targets such as bacteria and mitochondria were filtered 484 out based on the preliminary assemblies of male and female genome sequences using a GC-coverage 485 (proportion of GC bases and node coverage) plot-based method by blobtools (v0.9.19) [67] (Fig. 6), 486 resulting in total 400,520,654 and 453,725,764 "clean reads" for male and female mite, respectively. 487 The male "clean reads" were re-assembled and optimized up to scaffold level using the 488 VelvetOptimiser (v2.2.5) with the velvet parameters set to '-min\_contig\_lgth 200 and -ins\_length 489 1105'.

## **4**90 **Genome annotation**

To find, classify and mask repeated sequences in the assembled male genome, a *de novo* repeat library was first built using Repeatmodeler (A. F. A. Smit and P. Green, unpublished) with '-database' function followed by Repeatmasker (A. F. A. Smit and P. Green, unpublished) using default setting for *de novo* repeated sequences prediction. Then, a homology-based prediction of repeated sequences in the genome was achieved using Repeatmasker with default setting to search against RepBase repeat library issued on January 13, 2014. For non-interspersed repeated sequences, we ran Repeatmasker with the '-noint' option, which is specific for simple repeats, micro satellites, and low-complexity repeats.

**4**99 RNA-seq reads obtained from all samples were aligned to the masked genomic scaffolds to  $\vec{500}$ determine the exon-intron junctions using Tophat (v2.011) with default setting [69]. Cufflinks (v0.8.2) 501 [70] used the spliced alignments with default setting to reconstruct 44,614 transcripts from which 3<u>4</u>2 12,298 transcripts with intact coding sequences were selected by a Perl script developed by Liu et al. 503 [71]. Thee *ab initio* gene prediction programs, including Augustus (v3.0.3) [72], SNAP (v2013-11-29) <u></u> [73] and Genemarker (v2.3e) [74] were used for *de novo* gene predictions. Augustus and SNAP were 505 trained based on the selected intact coding sequences with default setting, whereas GeneMark [74] **5**06 was self-trained with '--BP OFF' option. We ran Augustus, SNAP, and Genemarker with default **5**07 setting, and predicted 32,561, 67,258, and 79,928 gene models in the masked genomic scaffolds, <del>5</del>08 respectively (Supplementary Table 2).

We also generated an integrated gene sets using MAKER v2.31.4 [75] pipeline. The MAKER pipeline runs Augustus, SNAP and Genemarker to produce *de novo* gene predictions, and integrates them with the evidence based predictions. They were generated by aligning all Cufflinks assembled transcript sequences and the invertebrate RefSeq protein sequences (downloaded on May 17, 2014 from NCBI) to the masked male mite genome by BLASTN and BLASTX, respectively. The MAKER pipeline was run with '-RM\_off' option to turn all repeat masking options off, and all parameters in control files were left with their default settings.

Genes identified by *de novo* prediction, which did not overlap with any genes in the integrated gene sets, were also added to the final gene set if they showed significant hits (BLASTP E-value < [57] 1e-5) to SwissProt proteins or could be annotated by Interproscan (v4.8) [76] with InterPro superfamily database (v43.1) using '-appl superfamily -nocrc' options.

13

61

#### 520 ncRNA annotation

521 In this analysis, we annotated four types of ncRNA: transfer RNA (tRNA), ribosomal RNA (rRNA),
522 microRNA, and small nuclear RNA (snRNA). Genes encoding tRNA were predicted by trnascan-SE

 $5\frac{4}{5}3$  (v1.3.1) [77] with eukaryote parameters, and rRNA genes were identified by aligning the rRNA

524 template sequences from invertebrates (database: SILVA 119) to the *T. mercedesae* genomic DNA

 $5\overline{2}5$  using BLASTN with an E-value cutoff of 1e-5. Genes encoding miRNA and snRNA were inferred

5 $\frac{8}{26}$  by the Infernal software (v1.1.1) [78] using release 12 of the Rfam database with '--cut\_tc' option.

## **527** Protein functional annotation

We performed the initial and principal domain annotation with the Pfam database (release 27) using the hmmscan in HMMER v3.1b1 with default settings. Additional domains (superfamily, Gene3d, Tigrfams, Smart, Prosite, and Prints domain models) and domain/motif based GO term were assigned using InterProScan search against InterPro database (v43.1) with '-cli -nocrc -goterms -iprlookup' options. We used Blast2GO pipeline (v2.5) [79] to further annotate proteins by Gene Ontology (GO)

We used Blast2GO pipeline (v2.5) [79] to further annotate proteins by Gene Ontology (GO) terms. In the first step, we searched the nr database with BLASTP using a total of 15,190 protein sequences as queries. The E-value cutoff was set at 1e-6 and the best 20 hits were collected for annotation. Based on the BLAST results, Blast2GO pipeline then predicted the functions of proteins to assign GO terms, and merged the InterProScan deduced domain/motif based GO terms into these BLAST based annotations.

The metabolic pathway was constructed based on the KAAS (KEGG Automatic Annotation Server) online server [80] using the recommended eukaryote sets, all other available insects, and *I. scapularis*. The pathways in which each gene product might be involved were derived from the best KO hit with BBH (bi-directional best hit) method.

## **543 GO enrichment**

We performed the GO enrichment analyses of gene sets with Fisher's exact test embedded in the Blast2GO desktop version (v2.8). If not specifically stated, the *P*-values were corrected according to the critical FDR. The enrichments were tested by comparing the GO terms with the pooled set of GO terms of all *T. mercedesae* proteins.

# **548** Species tree phylogenetics

5449 We first aligned orthologous protein sequences with Mafft (v7.012b) [81] or Kalign (v2.0) [82], and <del>5</del>50 then used Gblocks (v0.91b) [83] to automatically eliminate the divergent regions or gaps prior to  $\frac{44}{5451}$ phylogenetic analysis. However, we manually trimmed the aligned sequences for big gene sets. The **5**52 best substitution models of amino acid substitution were determined for the alignments by Prottest <sup>4</sup><sub>2</sub>73 (v3.4) with parameters set to "-all-matrices, -all-distributions, -AIC" [84]. Then, phylogenetic trees 54554 were constructed using maximum likelihood methods (Phyml, v3.1) [85] or Bayesian methods 5\$5 (MrBayes, v3.2.3) [86]. In addition, a neighbor-joining method was also used for building the 556 distance-based trees using MEGA (v6.06) [87].

# **5**<sup>3</sup>/<sub>2</sub>7 **Protein data sets of reference genomes**

Protein data sets of the following arthropod genomes were used as references: *D. melanogaster* (fruit
fly; GOS release: 6.03) [88], *A. mellifera* (honey bee; GOS release: 3.2) [62], *T. urticae* (spider mite;
GOS release: 20140320) [15], *Stegodyphus mimosarum* (velvet spider; GOS release: 1.0) [89], *I.*

- 561 scapularis (black-legged tick; GOS release: 1.4) [28], *M. occidentalis* (predatory mite; GOS release:
- 60
- 61 62

562 1.0) [21]. Caenorhabditis elegans (nematode; GOS release: WS239) [90] was used as the outgroup. 5¢3 Domain, GO, and KEGG annotation of proteins in the reference species (if required) was conducted 564 using the same methods as those used for *T. mercedesae*.

#### 5**¢**5 Gene family phylogenetics

566 Since the rapid evolution of acariform mites may challenge phylogenetic analyses due to long-branch 567 attraction [91], we used a very strict E-value (1e-50) when performing a reciprocal BLASTP to gate 568 out the most variant orthologous genes across all genomes tested. The reciprocal BLAST search 569 resulted in identification of a total of 926 highly conserved one-to-one orthologs in all eight genomes. \$<sup>1</sup>/<sub>2</sub>0 Each of these orthologous groups was aligned using Mafft in "-auto" option. These alignments were 571 trimmed by Gblocks and concatenated into the unique protein superalignments. ProtTest determined <u></u>\$<u>7</u>2 the best-fit substitution model of LG with invariant sites (0.109) and gamma (0.913) distributed rates 573 using parameters as above before conducting the phylogenetic analysis with Phyml.

#### Analysis of gene family expansion and positive selection

574 535 Orthologous gene families between T. mercedesae and six reference arthropods were defined based 376 on OrthoMCL (v1.4) [93] clustering. We used CAFE (v3.1) [94] to infer the gene family expansion 21 5777 and contraction in T. mercedesae against all reference arthropods or against Parasitiformes (I. **3**78 scapularis and M. occidentalis). The ultrametric species tree used in CAFE analyses was created as <u>5</u>249 described in Gene family phylogenetics section.

580 We also calculated  $\omega$  (dN/dS) ratios for 1,865 one-to-one orthologs defined by OrthoMCL using  $\frac{2}{28}$ codeml in the PAML package with the free-ratio model. Branches with  $\omega > 1$  are considered under **5**82 positive selection. The null model used for branch test was the one-ratio model, where  $\omega$  was the <del>58</del>3 same for all branches. The null model used for branch test was the one-ratio model (nssites = 0; <u>3</u>84 model = 0) where  $\omega$  was the same for all branches. Kappa and omega values were automatically 585 estimated from the data, when clock was set to be entirely free to change among branches. P-value 3<u>4</u>6 was determined twice using the log-likelihood difference between the two models compared to  $\chi^2$ 587 distribution with the difference in number of parameters between one-ratio and free-ratio models. To <del>3</del>88 estimate significance with the P-value, likelihood-ratio test (LRT) was used to compare lnl values for 589 each model and test if they are significantly different. The differences in log-likelihood values **5**90 between two models were compared to chi-square distribution with degree of freedom equal to the 512 difference in the number of parameters for two models. Measurement of dS was assessed for <del>5</del>92 substitution saturation, and only dS values < 3.0 were maintained in the analysis for positive <sup>44</sup> 5493 selection. Genes with high ( $\omega > 10$ ) were also discarded.

#### **59**4 De novo transcriptome assembly and estimation of the transcript abundance

All RNA-seq reads mapped to the honey bee transcripts were filtered out first. Then, all RNA-seq 5496 samples in Supplementary Table 1 were individually *de novo* assembled by Trinity (v20131110) [95] 597 with default setting. We used a RSEM [96] software package to estimate the expression levels 598 (abundance) of *de novo* assembled transcripts and isoforms with default setting.

#### 599 Analysis of RNA-seq data

6**0** After further removing the RNA-seq reads corresponding to DWV sequence, we aligned the cleaned 601 reads to the assembled T. mercedesae genome using Tophat with default setting. Then, Htseq-count 602 in the Htseq Python package (v0.6.1) [97] was used to obtain raw read counts, with the default 603 union-counting mode and option '-a' to specify the minimum score for the alignment quality. The

- 60 61
- 62 63

604 raw read count for each sample was then subject to further differential expression analysis using the 6¢5 EdgeR (v3.0) Bioconductor package [98]. We excluded mRNAs without at least one count per 606 million in the replicates (low overall sum of counts) from the analyses as previously suggested [99]. 6₫7 We then normalized the library sizes of all samples according to the trimmed mean of M-values 6**@**8 method, and dispersion was estimated from the replicates using the quantile-adjusted conditional 609 maximum likelihood method. Pairwise comparisons of differential gene expression between the 610 RNA-seq samples were performed using the function of Exact test. We used the corrected FDR **61**1 P-value < 0.01, and logFC > 1 and logFC < 1 cut-offs for significance.

# 612 **qRT-PCR**

6133 We carried out qRT-PCR reactions, each in triplicate, using an Applied Biosystems 7500 Fast 6**‡**4 Real-Time PCR System and 2X KAPA SYBR FAST qPCR Master Mix (KAPA Biosystems Woburn, 615 MA). To perform the absolute quantification of DWV RNA, we first prepared standard curves for **6**76 DNA corresponding to DWV target RNA. The target DNA was prepared by PCR followed by the gel 6<u>1</u>7 extraction. The DNA concentration was measured using Nanodrop 2000 spectrophotometer (Thermo 618 Scientific, USA) to calculate the original copy number by a formula; Copy number = DNA 619 concentration (ng/µl)  $\times$  6.02  $\times$  10<sup>23</sup> (copies/mol) / length (bp)  $\times$  6.6  $\times$  10<sup>11</sup> (ng/mol), in which 620  $6.6 \times 10^{11}$  ng/mol is the average molecular mass of one base pair, and  $6.022 \times 10^{23}$  copies/mol is the 624 6221 6222 Avogadro's number. Linear standard curves were then generated using target DNA of  $10^5$ – $10^9$  copy number per reaction followed by plotting the Ct values against log values of the copy number. After 623 28 624 reverse transcription, the copy number of target RNA in a sample was estimated using the standard curve above. To carry out the relative quantification, we compared the relative expression levels of 625 the target mRNA to Ef-1 $\alpha$  mRNA as the internal reference using the 2<sup>- $\Delta\Delta$ Ct</sup> method. All primers used 31 626 for qRT-PCR are listed in Supplementary Table 28.

# 627 Proteomic analysis

<u>34</u>8 Pools of male or female ites were lysed by sonication in 0.1 % (w/v) Rapigest (Waters MS 629 technologies) in 50 mM ammonium bicarbonate. Samples were heated at 80 °C for 10 min, reduced 630 with 3 mM DTT at 60 °C for 10 min, cooled, then alkylated with 9 mM iodoacetamide (Sigma) for 631 30 min (room temperature) protected from light; all steps were performed with intermittent 632 41 6333 vortex-mixing. Proteomic-grade trypsin (Sigma) was added at a protein:trypsin ratio of 50:1 and incubated at 37 °C overnight. Rapigest was removed by adding TFA to a final concentration of 1 % ₿34 (v/v) and incubating at 37 °C for 2 hours. Peptide samples were centrifuged at 12,000 x g for 60 min 44 435 (4  $^{0}$ C) to remove precipitated Rapigest. The peptide supernatant was desalted using C<sub>18</sub> 636 reverse-phase stage tips (Thermo Scientific) according to the manufacturer's instructions. Samples ¢37 were desalted and reduced to dryness as above and re-suspended in 3 % (v/v) acetonitrile, 0.1 % (v/v) 6438 TFA for analysis by MS.

Peptides were analysed by on-line nanoflow LC using the nanoACQUITY-nLC system (Waters MS technologies) coupled with Q-Exactive mass spectrometer (Thermo Scientific). Samples were loaded on a 50cm Easy-Spray column with an internal diameter of 75  $\mu$ m, packed with 2  $\mu$ m C<sub>18</sub> particles, fused to a silica nano-electrospray emitter (Thermo Scientific). The column was operated at a constant temperature of 35 °C. Chromatography was performed with a buffer system consisting of 0.1 % formic acid (buffer A) and 80 % acetonitrile in 0.1 % formic acid (buffer B). The peptides were separated by a linear gradient of 3.8 – 50 % buffer B over 90 minutes at a flow rate of 300

16

60 61

62

63

646 nl/min. The Q-Exactive was operated in data-dependent mode with survey scans acquired at a 647 resolution of 70,000. Up to the top 10 most abundant isotope patterns with charge states +2, +3648 and/or +4 from the survey scan were selected with an isolation window of 2.0Th and fragmented by 649 higher energy collisional dissociation with normalized collision energies of 30. The maximum ion 650 injection times for the survey scan and the MS/MS scans were 250 and 50 ms, respectively, and the 651 ion target value was set to 1E6 for survey scans and 1E5 for the MS/MS scans. Repetitive 652 sequencing of peptides was minimized through dynamic exclusion of the sequenced peptides for 20s.

693 Thermo RAW files were imported into Progenesis LC-MS (version 4.1, Nonlinear Dynamics). 654 Runs were time aligned using default settings and using an auto selected run as reference. Peaks 655 were picked by the software using default settings and filtered to include only peaks with a charge 656 state between +2 and +7. Spectral data were converted into .mgf files with Progenesis LC-MS and 657 exported for peptide identification using the Mascot (version 2.3.02, Matrix Science) search engine. <del>6</del>58 Tandem MS data were searched against translated ORFs from T. mercedesae, Apis mellifera 6<u>5</u>9 (OGSv3.2) [101] and Deformed Wing Virus (Uniprot 08 2016) (total; 30,666 sequences; 12,194,618 660 residues). The search parameters were as follows: precursor mass tolerance was set to 10 ppm and 661 fragment mass tolerance was set as 0.01Da. Two missed tryptic cleavages were permitted. 662 Carbamidomethylation (cysteine) was set as a fixed modification and oxidation (methionine) set as 6<u>6</u>3 variable modification. Mascot search results were further validated using the machine learning 664 algorithm Percolator embedded within Mascot. The Mascot decoy database function was utilised and £65 the false discovery rate was < 1%, while individual percolator ion scores >13 indicated identity or **66**6 extensive homology (P < 0.05). Mascot search results were imported into Progenesis LC–MS as 667 XML files. Peptide intensities were normalised against the reference run by Progenesis LC-MS and 668 these intensities are used to highlight relative differences in protein expression between samples. The 669 mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium via the 3<del>4</del> 3750 PRIDE [102] partner repository with the dataset identifier PXD004997.

#### **Data availability**

672 673 All sequence data we obtained and analyzed are deposited under the project accession number 674 41 6725 PRJNA343868 in NCBI.

Table 3 Comparison of the number of CYP2, 3, 4, and mitochondrial clan members in Insecta,
Crustacea, and Acari.

The data of four insects, *Anopheles gambiae*, *Aedes aegypti*, *Nasonia vitripennis*, and *Tribolium castaneum* are also included. Data referred to references [105] and this study. The numbers in parentheses are derived from previous report [42].

### 989 Figure legends

## 990 Figure 1 Images of Tropilaelaps mercedesae

991 (A) Three adult females of *T. mercedesae* infesting the 5th instar honey bee larva. (B) Ventral view992 of the nymph (immature female). (C) Ventral view of the adult female.

993

### 994 Figure 2 Comparative genomics.

9§5 (A) The species phylogeny was built from aligned protein sequences of 926 one-to-one orthologs in 996 Metaseiulus occidentalis, Tropilaelaps mercedesae, Ixodes scapularis, Stegodyphus mimosarum, 997 Tetranychus urticae, Drosophila melanogaster, Apis mellifera and Caenorhabditis elegans using a 998 maximum likelihood method. The tree was rooted with C. elegans. All nodes showed 100% <u>9</u>99 bootstrap support. Protein-coding genes were classified into the different categories. 1:1:1 orthologs 1000 and N:N:N orthologs represent the common orthologs with the same copy numbers and different 1001 copy numbers, respectively. Patchy orthologs are shared between more than one but not all species 1**00**2 (excluding those in the previous categories). Unclustered genes represent genes which were not 1003 classified into orthology cluster. Other categories include arthropod-, Arachnida-, Parasitiformes-, 1004 and species-specific genes. C. elegans was used as the outgroup for classification of the 1005 protein-coding genes. (B) The number of gene families shared between T. mercedesae, M. 1006 occidentalis, I. scapularis, and other reference species (S. mimosarum, T. urticae, D. melanogaster, 1007 A. mellifera and C. elegans) by orthoMCL classification algorithm.

# 1009Figure 3 Phylogenetic tree of T. mercedesae, I. scapularis, and D. melanogaster gustatory1010receptors.

 $10\frac{1}{2}$ Phylogenetic tree of *T. mercedesae* (red), *I. scapularis* (blue), and *D. melanogaster* (green) gustatory $10\frac{1}{2}$ receptors (GRs) was constructed by a maximum likelihood method. Two clusters of fruit fly GRs $10\frac{3}{5}$ responding to sugar and CO<sub>2</sub> are indicated. The tree was rooted at the middle point.

10154

1008

# 1015 Figure 4 Phylogeny of T. mercedesae, M. occidentalis, and D. melanogaster cytochorme P450.

1036 The phylogenetic tree was constructed by maximum likelihood method and rooted at the middle 1036 point. P450s are clustered to CYP2, CYP3, CYP4, and mitochondrial clans are shown by red, green, 1038 blue, and dark yellow branches, respectively. *D. melanogaster* (DmCYP), *T. mercedesae*, and *M.* 1039 *occidentalis* P450s are indicated by dark green, purple, and dark yellow, respectively. *T. mercedesae* 10320 and *M. occidentalis* P450s are designated by protein IDs.

1021

# 1 $\frac{47}{22}$ Figure 5 Volcano plot of proteins in the male and female mites.

 Proteins identified in the male and female mites by proteomic analysis are plotted according to the ratios of amounts present in male to female. Proteins abundant in the male and female are indicated by blue and red circles, respectively. Some of the representative proteins are indicated with the names and accession numbers of the best Blast hits.

10,27

## **1028** Figure 6 %GC-coverage plots of the preliminary assembled genomes of male and female.

1 $\frac{57}{28}$  Individual contigs are plotted based on their GC content (x-axis) and their node coverage (y-axis; 1 $\frac{530}{28}$  logarithmic scale). Contigs are colored according to the taxonomic order of their best Megablast hit

27

60 61

- 63
- 64 65

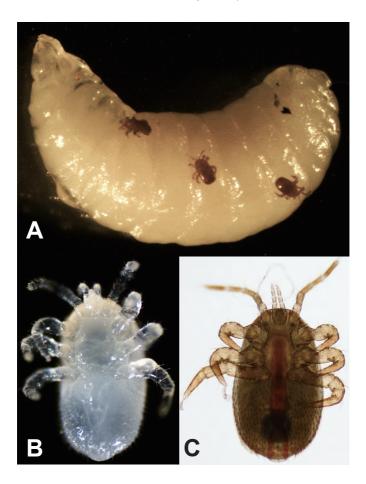

- 1031to the NCBI nt database (with E-value cut off < 1e-5). Contigs without the annotation are in gray. % $10\frac{1}{3}2$ GC plots against node coverage for the (A) male and (B) female contigs are shown in.

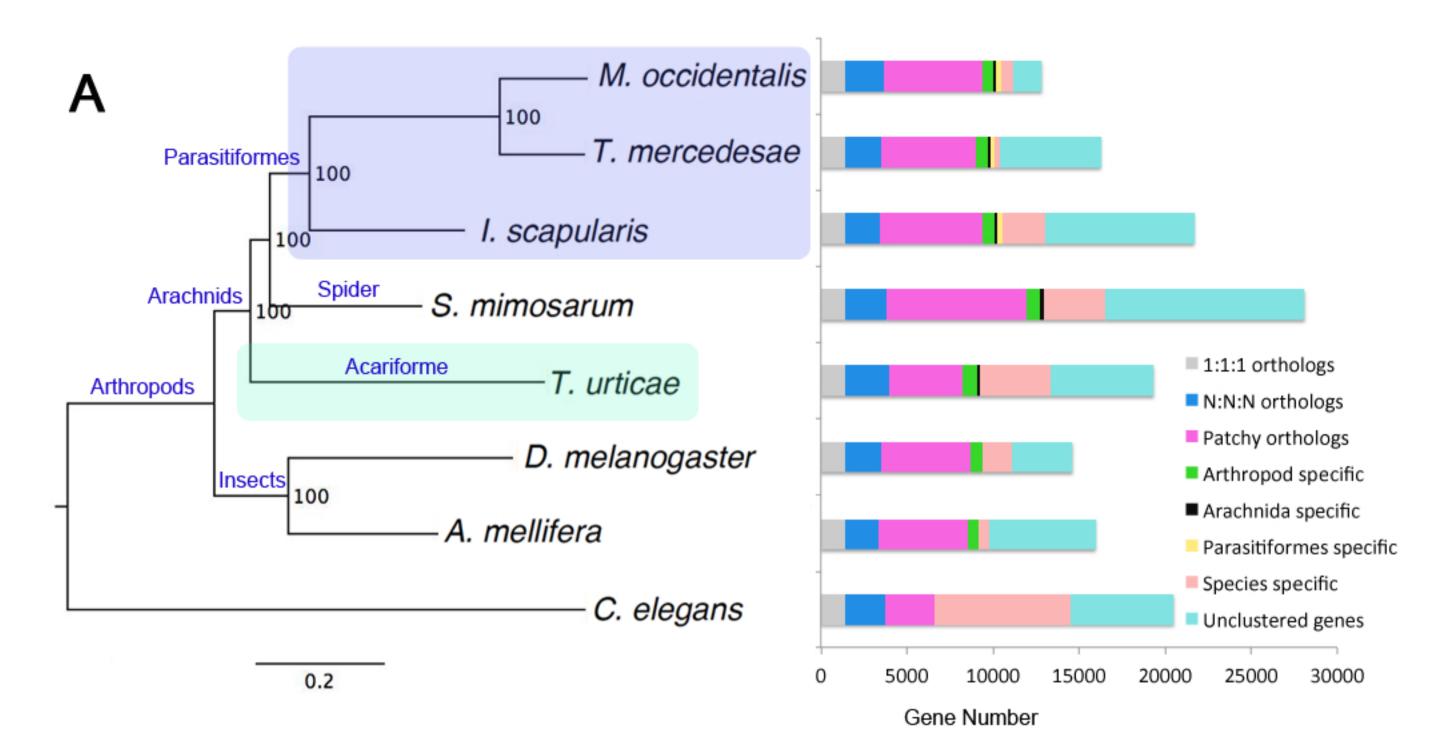

## 10<sup>4</sup>/<sub>2</sub>4 Figure 7 Classification of DWV in the *T. mercedesae* tanscriptomes.

 $\frac{3}{25}$  The Bayesian phylogeny was constructed using Mrbayers based on the amino acid sequences of  $\frac{3}{26}$  complete DWV genomes assembled from the adult males, adult females and nymphs transcriptomes  $\frac{3}{27}$  (DWV weixi strain complete genome male, DWV weixi strain complete genome female, and DWV  $\frac{3}{29}$  weixi strain complete genome nymph) as well as seven other DWV strains (type A variant:  $\frac{1}{29}$  NC\_005876.1, NC\_004830.2, JQ\_413340, and ERS657948; type B: KC\_786222.1 and 1040 NC\_006494.1; type C: ERS657949). The tree was rooted with Formica exsecta Virus 1  $\frac{1}{24}$  (NC\_023022.1) and Sacbrood Virus (NC\_002066.1).
