52 53 Abstract

54 55 Background

56
57
58 *Rhodiola crenulata*, one of the well-known Tibetan medicinal herb, is mainly grown in
59
60
61
62
63
64
65

1 high-altitude regions of Tibet, Yunnan and Sichuan provinces in China. In the past few
2
3 years, increasing published studies on pharmacological activities of *R. crenulata*, have
4
5 strengthened our understanding into its active ingredient composition, pharmacological
6
7 activity and mechanism of action. The findings also provided strong evidences
8
9 supporting the important medicinal and economical values of *R. crenulata*. Meanwhile,
10
11 some *Rhodiola* species are becoming endangered because of overexploitation and
12
13 environmental destruction. However, little is known about the genetic and genomic
14
15 information of any *Rhodiola* species.
16
17
18
19
20
21

22 **Findings**

23 Here, we reported the first draft assembly of *R. crenulata* genome, which was 344.5
24
25 Mb (25.7Mb Ns), accounting for 82% of the estimated genome size, with the scaffold
26
27 N50 length of 144.7 kb and the contig N50 length of 25.4 kb. The *R. crenulata* genome
28
29 was not only highly heterozygous but also highly repetitive with ratios of 1.12% and
30
31 66.15%, respectively, based on the *k*-mer analysis. Furthermore, 226.6 Mb transposable
32
33 elements were detected, of which 77.03% were long terminal repeats. In total, 31,517
34
35 protein-coding genes were identified, capturing 86.72% of expected plant genes in
36
37 BUSCO. Additionally, 79.73% of protein-coding genes were functionally annotated.
38
39
40
41
42
43
44
45
46
47

48 **Conclusions**

49 *R. crenulata* is an important medicinal plant and also a potentially interesting model
50
51 species for studying the adaptability of *Rhodiola* species to extreme environments. The
52
53 genomic sequences of *R. crenulata* would be useful for understanding the evolutionary
54
55 mechanism of stress resistance gene and biosynthesis pathways of the different

Sample collection and Sequencing

According to the *protocol 1* (**Additional file 2**), genomic DNA was isolated from the leaf tissue of a single male *R. crenulata* (**Fig. 1**; NCBI taxonomy ID: 242839), which was collected from Shangri-La, located in the northwest of Yunnan province, China.

Subsequently, three paired-end libraries with insert size 250 bp, 500 bp, 800 bp and three mate-pair libraries (5 kb, 10 kb, 20 kb) were constructed with the standard protocol provided by Illumina (San Diego, USA) and sequenced on an Illumina HiSeq 2000/4000 platform using a whole genome shotgun sequencing (WGS) strategy. A total of 162.08 Gb (~380X) raw sequence reads were generated (**Additional file 1: Table S1**). To reduce the effect of sequencing errors to the assembly, SOAPfilter (Version 2.2), a package from SOAPdenovo2 [7], was used to filter reads with adapters, low quality, undersize insert size and PCR duplication with parameters ‘-y -z -p -M 2’. Finally, 123.47 Gb (~290X) clean data were obtained (**Additional file 1: Table S1**).

RNA were extracted from the root, stem and leaf tissues, respectively, of a single male *R. crenulata*, which was collected from the Jade Dragon Snow Mountain, located at the northwest of Yunnan province, China, according to the *protocol 2* (**Additional file 2**).

Single-end libraries were constructed subsequently using standard protocol provided by BGI (BGI-Shenzhen) and then sequenced on the BGISEQ-500 platform. Totally, 13.54 Gb raw data was obtained, and after filtering by SOAPnuke (Version 1.5.6) (<https://github.com/BGI-flexlab/SOAPnuke>) with parameters “-l 10 -q 0.5 -n 0.01 -f AGTCGGAGGCCAAGCGGTCTTAGGAAGACAA -Q 2”, we finally got 13.23 Gb high-quality clean data (**Additional file 1: Table S2**).

Assembly

1
2
3 Firstly, the genome size, 420.2 Mb, was estimated based on the 17-mer analysis [8]
4
5
6 using 34.4 Gb clean data from 250 bp-insert library, as well as the repetitive and
7
8
9 heterozygous ratio with 66.15% and 1.12%, respectively (**Additional file 1: Table S3;**
10
11
12 **Fig. S1**). Given the high heterozygosity, Platanus (Version 1.2.4) [9], which is efficient
13
14 for the assembly of highly heterozygous genomes, was used to assemble the genome
15
16 by performing “assemble, scaffold, gap_close” modes orderly with “k=35”. As a result,
17
18 345.1 Mb (containing 65.9 Mb Ns) draft assembly with the contig N50 length of 6.3 kb
19
20
21 and the scaffold N50 length of 145.1 kb was generated (**Additional file 1: Table S4**).
22
23
24 To further improve the quality of our assembly genome, GapCloser (Version 1.10) [7]
25
26 was implemented with all of six libraries data. Finally, we got the 344.5 Mb (containing
27
28 25.7 Mb Ns) of assembly genome, representing for 82% of the estimated genome size,
29
30
31 with the contig and scaffold N50 length of 25.4 kb and 144.7 kb, respectively (**Table**
32
33
34 **1**). Meanwhile, we also ran other prevalent *de novo* assemblers, such as SOAPdenovo2
35
36
37 [7], ABySS (Version 1.9.0) [10] with various modifications of parameters. But the
38
39
40 results based on these assemblers were not better (**Additional file 1: Table S4**). More
41
42
43 methodological information is available in the *protocol 3* (**Additional file 2**).
44
45
46
47
48

Table 1. Statistics of the final assembly using Platanus and Gapcloser.

| Type | Scaffold | Contig |
|-------------------|-------------|-------------|
| Total number | 150,003 | 161,878 |
| Total length (bp) | 344,513,827 | 318,807,120 |
| N50 length (bp) | 144,749 | 25,360 |
| N90 length (bp) | 1,003 | 877 |

| | | |
|-----------------|-----------|---------|
| Max length (bp) | 1,309,315 | 300,573 |
| GC content (%) | 39.68 | 39.68 |

Repeat annotation and gene prediction

A combination of *de novo* and homolog-based methods were conducted to identify the transposable elements (TEs) and predict the protein-coding genes in *R. crenulata* genome according to the *protocol 3* (**Additional file 2**), which was also illustrated in

Fig. 2.

Briefly, in terms of the repeats detection, firstly, RepeatScout (Version 1.0.5) [11], LTR-FINDER (Version 1.0.5) [12] and RepeatModeler (Version 1.0.5) [13] were used to build *de novo* library on the basis of our genome sequences and then by using the library as database, RepeatMasker (Version 3.3.0) [13] was utilized to classify the types of repetitive sequences (**Additional file 1: Table S5**). On the other hand, TEs in DNA and protein levels were identified by aligning genome sequences against Repbase TE library (Version 17.01) [14, 15] and TE protein database with RepeatMasker and RepeatProteinMask (Version 3.3.0) [13] (**Additional file 1: Table S6**). Overall, 226.6 Mb of TEs (65.77% of the assembly) were detected, containing 174.6 Mb (50.67% of the assembly) LTR (**Fig. 3a; Additional file 1: Table S6**).

Before gene prediction, TEs observed above were masked to reduce the interference.

Regarding the *de novo* gene prediction, Augustus (Version 2.5.5) [16, 17] and GlimmerHMM (Version 3.0.1) [18] were conducted with Arabidopsis training set, and 31,005 and 34,586 protein-coding genes were predicted, respectively (**Fig. 3b; Additional file 1: Table S7**). With respect to the homolog-based methods, because of

1 the lack of accessible genome sequences in family *Crassulaceae*, we downloaded the
2
3 protein sequences of model organism *Arabidopsis thaliana*
4
5 (<https://www.ncbi.nlm.nih.gov/genome/?term=Arabidopsis+thaliana>) and relatively
6
7 close-related species – *Fragaria vesca*
8
9 (https://www.ncbi.nlm.nih.gov/genome/3314?genome_assembly_id=34435), *Prunus*
10
11 *mume* (https://www.ncbi.nlm.nih.gov/genome/13911?genome_assembly_id=44389
12
13) and *Prunus persica*
14
15 (https://www.ncbi.nlm.nih.gov/genome/388?genome_assembly_id=28754) in *rosids*,
16
17 and then aligned these against the repeat-masked genome using BLAT [19]. GeneWise
18
19 (Version 2.2.0) [20], whose algorithm was derived from a principled combination of
20
21 hidden Markov models, was subsequently used to merge these mapping results and
22
23 predict gene structures, resulting in 36,495, 27,034, 28,767 and 25,976 protein-coding
24
25 genes, respectively. In addition, each average length of CDS, exon and intron predicted
26
27 in different methods were similar (**Fig. 3b; Additional file 1: Table S7**). Then we
28
29 performed GLEAN [21] to integrate genes predicted above and got a non-redundant
30
31 gene set, containing 28,981 protein-coding genes. Also, we discarded those genes with
32
33 overlapping ratio less than 0.8 when comparing with homolog-based evidence. 27,107
34
35 genes were remained. Additionally, to further improve the credibility, sequenced
36
37 transcriptomes data from three *R. crenulata* tissues were mapped to the consensus gene
38
39 set by TopHat (Version 2.1.0) [22], and then Cufflinks (Version 2.2.1) [23] was
40
41 executed to assemble and merge transcripts based on the mapping results. Finally, the
42
43 gene set with 31,517 protein-coding genes was generated, of which 79.73% genes can

2
3 databases, and using InterProScan (Version 4.7) [27, 28] (**Additional file 1: Table S8**).
4
5

6 **Completeness of the gene set and assembly**

7

8
9 To evaluate the completeness of the gene set and assembly, BUSCO [29] was
10
11 performed with “-OGS” and “-genome” modes, respectively. The results showed that
12
13 86.72% of reference genes were captured as complete single-copy BUSCOs when
14
15 searching our gene set; meanwhile, regarding the assembly, 91.63% of the 956 expected
16
17 plant genes were detected as complete (**Table 2**). Additionally, RNA sequence reads
18
19 were mapped to our genome assembly by TopHat (Version 2.1.0) [22] and the average
20
21 mapping ratio was almost 81.5% (**Additional file 1: Table S9**).
22

51
52 In summary, the *R. crenulata* genome that we have sequenced, assembled and
53
54 annotated here, was the first one in the Genus *Rhodiola*, and even in the family
55
56 *Crassulaceae*. The *R. crenulata* genome would serve as an important resource for
57

10

11 **Figure legends**

12 **Figure 1. Example of *R. crenulata* (image from Shifeng Li).**

13
14 **Figure 2. An overview of the annotation workflow.** The workflow begins with
15 assembled genomic sequences, and it produces results of the repeat annotation, protein-
16 coding gene prediction and functional annotation. (a) Repeat annotation. Repeats in the
17 genome are detected in two different methods: *de novo* and homolog-based. In the *de*
18 *novi* methods, RepeatScout, LTR-FINDER and RepeatModeler are used to build *de*
19 *novi* repeat libraries and further classified by RepeatMasker; In the homolog-based
20 methods, RepeatMasker and RepeatProteinMask are performed to search TEs by
21 aligning sequences against existed libraries. (b) Gene prediction. Before the gene
22 prediction, TEs are totally masked. Augustus and GlimmerHMM are used to perform
23 *de novo* prediction; BLAT and GeneWise are executed to predict gene models based on
24 the homologous protein sequences. (c) GLEAN is performed to obtain consensus gene
25 set. (d) In combination with the clean RNA sequenced reads, a more comprehensive
26 gene set is integrated finally. (e) Estimation of the completeness of gene set by using
27 BUSCO. (f) Functional annotation.

28

Dear Editor,

Please find enclosed our manuscript entitled “*Draft genome of the Tibetan medicinal herb, Rhodiola crenulata*”, which we wish to submit for publication as a DataNote in *GigaScience*. All co-authors have approved the final version of this manuscript and there is no financial interest or other conflict to declare. We certify that the submission is original work and is not under review with another journal.

Rhodiola crenulata, one of the well-known Tibetan medicinal herb, is mainly grown in high-altitude regions of Tibet, Yunnan and Sichuan provinces in China. In the past few years, increasing published studies on pharmacological activities of *R. crenulata*, have strengthened our understanding into its active ingredient composition, pharmacological activity and mechanism of action. The findings also provided strong evidences supporting the important medicinal and economical values of *R. crenulata*. Meanwhile, some *Rhodiola* species are becoming endangered because of overexploitation and environmental destruction. However, little is known about the genetic and genomic information of any *Rhodiola* species. Here, we sequenced and assembled the genome sequences of *R. crenulata*, which is also the first sequenced species in family *Crassulaceae*. A total of 162.08 Gb (~380X) raw sequence reads were generated and 344.5 Mb (containing 25.7 Mb Ns) of assembly genome, representing for 82% of the estimated genome size, with the contig and scaffold N50 length of 25.4 kb and 144.7 kb, respectively, was obtained. We also provided a detailed assessment of the genome completeness, and carried out transposable element, protein-coding genes prediction for the genome assembly. The predicted genes were also functionally annotated.

We believe that the *R. crenulata* genome that we have sequenced, assembled and annotated here, would serve as an important resource for comparative genomic study and also further investigation of the adaptability of *Rhodiola* species in extreme

environment and the biosynthesis pathways of pharmacologically active metabolites in *Rhodiola* species.

I hope you will find our study of interest and look forward to hearing from you.

Sincerely yours,

Xin Liu, PhD

liuxin@genomics.cn
