ABSTRACT:**Introduction**

Physical activity is a cornerstone in rehabilitation of Type 2 diabetes patients (T2D). Development of effective long-term and low cost strategies to keep these patients' physically active is needed. However, maintaining physical activity behaviour is difficult once formalised interventions end. One potentially effective strategy includes structured exercise training supported by mobile technology and remote feedback.

The aim is to investigate whether mobile health support using the InterWalk application for smartphones is effective in increasing the physical activity level in persons with T2D over time compared to standard care.

We investigate if a rehabilitation programme with interval walking training using the InterWalk app is superior to Danish municipality-based rehabilitation in increasing moderate-and-vigorous physical activity level in patients with T2D across 52 weeks. Secondary, we hypothesize that a motivational programme added from end of intervention to 52-weeks further increases level of physical activity in everyday life in patients with T2D.

Methods and analysis

The trial is a parallel-group, open-labelled, randomised controlled trial with 52-week follow-up including patients with T2D. The primary outcome is change in moderate-and-vigorous physical activity. The key secondary outcome includes motivation for physical

activity behaviour change. Exclusion criterion is medical contraindication to exercise. We include up to 246 patients and randomly allocate them into a control (standard group exercise) or an experimental group (8-12 weeks of interval walking training supported by the smartphone-based InterWalk application) in a 1:2 fashion. After intervention, the experimental group is randomly allocated into two follow-up conditions with unsupervised interval walking training with or without motivational support until 52-week follow-up. Data is analysed by the Intention-To-Treat principle.

Ethics and Dissemination

The local regional Research Ethics Committee in Denmark (H-1-2014-074) and the Danish Data Protection Agency (j.nr. 2014-54-0897) has approved the trial. Positive, negative or inconclusive results will be disseminated in scientific journals and conferences.

Trial registration: NCT02341690

Keywords: Type 2 diabetes, Rehabilitation, Interval walking Training, Physical activity, Behaviour maintenance

STREGTHS:

- The trial is the largest of its kind, and meets the criteria for high quality randomized controlled trials with central randomization, multi centre setup and use of valid and reliable measures.

Effect of Interval walking on type 2 diabetics

BMJ Open

- The trial gives knowledge to the lacking evidence on pragmatic designed trials and secures directly implementable interventions in clinical practice
- The trial visualises the importance of individual motivation regarding behavioural change with physical activity when diagnosed with type 2 diabetes

LIMITS:

- We are aware that the design of the trial with a multi centre setup may cause variation in the testing situations were the performance can depend in the individual health professional. Accordingly, all results will be interpreted conservatively.

INTRODUCTION

Physical activity (PA) is a cornerstone in the clinical care of patients with type 2 diabetes (T2D).[1] PA activity has beneficial effect on glycaemic control and other key metabolic risk factors [2,3], as well as improvements in quality of life.[4,5] Furthermore, supervised long-term PA interventions have proven effective in improving glycaemic control.[2,6] However, experimental evidence does not support the efficiency of advice about physical activity alone.[7] As the number of patients with T2D is estimated to rise to 500 million by 2030 worldwide [8,9] the implementation of structured, long-term and supervised exercise regimes constitutes a large societal challenge and is not feasible. Thus, novel strategies to increase physical activity among patients with T2D are needed.

Smartphones have been used as a tool to register exercise, diet, weight and plasma glucose levels, but the evidence for using a smartphone as an exercise device and a self-management tool in the diabetes care is lacking.[10] However, emerging evidence suggest that eHealth solutions using information and communication technologies [11] can educate and engage patients with T2D in long-term self-management.[12–14] Due to the large ingress and ownership of smartphones, a smartphone-supported approach could prove feasible in increasing physical activity among patients with T2D and accommodate the increasing prevalence of T2D.

Efficiency of interval walking training (IWT) in patients with T2D has been established.[15] In the study by Karstoft and co-workers, IWT was administered and

1
2
3
4
5
6
7
8
9 monitored using a small exercise computer (JD-mate). IWT induced significant improvements
10 in physical fitness level, body composition and glycaemic control and in adherence of more
11 than 85% over a 16 weeks period.[15] The potential benefits of implementing eHealth
12 solutions in T2D management and the apparent health benefits of and adherence to IWT gave
13 rise to the development of the InterWalk application (InterWalk app) to deliver IWT.[16]
14
15
16
17
18

19
20 There is a lack of knowledge about the integration of PA in the everyday life
21 of the patient following rehabilitation interventions.[17] It is, however, known that
22 successful behavioural change depends on an on-going maintenance of individual
23 motivation regarding the behaviour and behavioural change itself.[18] Furthermore, time
24 since onset of diagnosis, unhealthy behaviour and own beliefs about the cause of the
25 problem, together with the number of previous attempts to change and support from
26 partners, peers and health professionals are of relevance.[18] This underlines the need for
27 new interventions with a direct focus on motivational support and self-control regarding
28 sustaining a newly acquired behavioural change with PA. To better target and structure
29 manageable interventions related to patients with T2D, understanding patients' individual
30 priorities and values are crucial. In this regard, knowledge of individual motivation and self-
31 efficacy to initiate behavioural changes becomes essential to understand.[18]

12

13 14 15 **Trial objective and hypothesis** 16

17 The objective of the trial is to investigate whether mobile support using the InterWalk
18 application for smartphones is effective in increasing the physical activity level in persons
19 with type 2 diabetes over time compared with a standard care rehabilitation program.
20
21
22

23 We investigate the effectiveness of the implementation of interval walking training using the
24 InterWalk application in the Danish municipality-based rehabilitation program and study
25 whether the interval walking training is superior to standard care in increasing moderate-
26 vigorous physical activity 52 after weeks. Furthermore, we expect that a motivational support
27 program added from end of the intervention to 52-weeks, will increase the physical activity
28 level in patients with type 2 diabetes and help maintaining a physically active everyday life
29 long-term.

20
21 The intervention is conducted at the health promotion centres in Danish
22 municipalities and hospitals that consecutively are included as cooperation partners. The
23 municipality of Copenhagen is the first collaborator in the trial. Patients are referred to
24 rehabilitation by their general practitioner (GP). Trained health professionals (physical
25 therapists, nurses and staff with a master's degree) working at the health promotion centres
26 recruit the patients, deliver the interventions and conduct all testing. The overall
27 organization of health care in Denmark is fully tax-financed with universal access to health
28 care services. The Danish model is described in detail elsewhere [21,22] and chronic
29 disease care (including T2D) management is in Denmark based in the Chronic Care
30 Model.[23]

43 Briefly, all patients diagnosed T2D can be referred to rehabilitation at either
44 an out-patient clinic, municipality or hospital level in Denmark by their GP. The
45 municipality based rehabilitation primarily includes non-complicated patients (~80% of all
46 patients) referred from GPs.[21] If complications or co-morbidities are present, patients are
47 referred to treatment at a specialized clinic at a hospital. Patients with a non-complicated

9 course of disease receive rehabilitation consisting of: 1) disease-specific patient education,
10 2) diet counseling, 3) smoking cessation and 4) exercise. The composition of the individual
11 rehabilitation program depends however on disease progression and on the rehabilitation
12 offered in the municipality-based program or at the hospital. The general focus is patient
13 empowerment, disease-related self-care and prevention of a decay of the functional
14 capacity of patients with T2D.

42 **Participants**

43 *Eligibility*

44 All non-complicated patients diagnosed with T2D (out-patients), referred to a health
45 promotion centre or hospital in the participating municipalities by their GP, are eligible if
46 more than 18 years of age. A flow chart of participants is presented in Figure 2.

The exclusion criteria are medical contraindications to exercise e.g. chronic complications in the locomotive apparatus, painful osteoarthritis or heart conditions.[24] Information is collected through medical records and at a screening interview with a health professional at the health promotion centre. Furthermore, patients are excluded if they do not want to be physically active in the rehabilitation setting or are already participating in other intervention studies at a health promotion centre. The patients have to be able to talk, read and understand the Danish language (for overview over in- and exclusion criterion, see Table 1).

Table 1. ELIGIBILITY CRITERIA

Inclusion criteria

- Diagnosed with type 2 diabetes
- Referred by General practitioner to a health promoting center in participating municipality or hospital

Exclusion criteria

- < 18 years of age
 - Medical contraindications to exercise
 - Already participating in other exercise trials
 - Does not talk and read Danish
-

If eligible, health professionals give oral and formalized written information with two days to consider participation in the trial. Written informed consent is obtained before any additional trial procedures. Enrolment was initiated in January 2015 and recruitment is terminated on December 15th 2016. Last-patient-last-visit is expected in December 2017.

Interventions

The trial is developed in collaboration with the health professionals from the municipality of Copenhagen in Denmark. The interventions are designed to reflect the clinical rehabilitation settings in Denmark in order to increase the likelihood of implementation of the programme following this trial, if proven superior. The investigators (LSV, CB and HL) led four workshops (16 hours in total) with the health professionals during year 2014, in which the interventions of the study and work routines were discussed in detail. Furthermore, all participating health professionals underwent a thorough education program (15 hours in total) involving all procedures and manuals in the trial. This was done to ensure a standardization of all procedures throughout the trial. In addition, consecutive workshops were and are held from the start of the trial (January 2014) every second month to secure all routines and education level for all health professionals throughout the trial. The applicability of the trial results is hereby increased, as the interventions are already part of the rehabilitation programme offered to patients with T2D in the municipalities.

The interventions in the trial consist of two phases (Figure 1). In phase one (8-12 weeks), patients are randomised to either a standard care group (control intervention) or an experimental group doing IWT using the InterWalk app. The present trial uses the standard care programme as control intervention and is conducted directly in the clinical

Effect of Interval walking on type 2 diabetics

BMJ Open

8
9 setting. All patients receive supervision across phase one. In phase two (40-44 weeks),
10 patients in the standard care group have no follow-up until 52 weeks post baseline. Patients
11 in the experimental intervention group are in phase two randomly allocated to either IWT
12 with or without motivational support (see section Experimental intervention – Interval
13 Walking with the InterWalk application). Additional rehabilitation care (co-interventions)
14 with disease-specific patient education, diet counseling and smoking cessation is offered to
15 all patients across the intervention groups. The interventions are summarized in Table 2.

Experimental intervention – Interval Walking with the InterWalk application

Patients allocated to the experimental intervention do interval walking after baseline test provided by health professionals (phase one). IWT is provided by health professionals to smaller groups of 3-12 patients. After the intervention period in phase two patients are allocated to either receive IWT without motivational support during follow-up (IWTgroup) or IWT with motivational support during follow-up (IWTsupport-group) (Figure 1). Trained health professionals conduct the IWT sessions (see below) and the motivational support in phase two. Table 2 gives an example of a typical week with interval walking in the experimental intervention group.

Interval Walking Training using The InterWalk Application

Interval walking training is performed using the InterWalk app, which works as a personal trainer as well as a monitoring unit allowing researchers to continuously and automatically monitor and store the physical activity level in a central database (Figure 3).[16]

Interval walking is personalized through a standardised eight-minute walking test, performed with the app before engaging in IWT.[25] The InterWalk app guides the user in IWT with repeated cycles of 3 minutes fast and 3 minutes slow walking. During Interval Walking Training (IWT) the InterWalk app provides the patient with continuous feedback on the walking speed. The patients are able to track exercise history and receive historic feedback on the quality of the IWT session using the app. The feedback system employs the

1
2
3
4
5
6
7
8 on-board accelerometer of the phone and GPS system to assess intensity and geographical
9 location. Information on training intensity, total number of steps per day, IWT-data and data
10 from the standardised walking test is stored in the smartphone or iPod and automatically
11 transmitted to the central database at the Danish Strategic Research Centre for Type 2
12 Diabetes (DD2) when connected to Wi-Fi or mobile data network.[16]

27
28 The patient receives a thorough introduction to the InterWalk app with follow-up
29 instructions. The introduction consists of information and test of the app and the patient can
30 ask clarifying questions if needed. A detailed manual regarding the InterWalk app is
31 extradited to each patient. The health professional provides technical guidance and helps the
32 patient to structure an everyday life with interval walking during phase one. Patients are
33 encouraged to perform IWT using the InterWalk app (see section: InterWalk walking
34 training using the InterWalk Application) as a minimum three times per week, 30 to 60
35 minutes per session, with two of the sessions taking place at the health promotion centre and
36 the third is conducted in the patient's everyday life environment. The aim is that all patients
37 are capable of continuing IWT using the InterWalk app at the end of phase one (Table 3).

Table 3, EXAMPLE OF EXPERIMENTAL INTERVENTION FOR ONE WEEK IN PHASE ONE

Weekday	Intervention at the Health promotion center	Independent training in own environment	Notes to health professionals
<i>Monday</i>	Duration: 90 minutes 1. Warm-up: short walk to the walking point (either a park or an area near the center) 2. Interval walking: every patient do interval walking with the InterWalk app for a minimum of 30 minutes. The health professionals guide and facilitate the walking. 3. Group conversation: takes place at the health promotion center after doing interval walking with all participation patients. Here different focus areas are discussed in the group. The health professional participates as a facilitators in the group conversation (examples of focus areas: weather conditions, motivation for exercise, social needs when waking, motivation for a physically active everyday life)		<ul style="list-style-type: none"> • Make sure to encourage doing interval walking alone or together with other patients participating in interval walking at the health promotion center. • If some of the patients need to do a new walking test help should be given during the intervention.
<i>Tuesday</i>	Rest day		
<i>Wednesday</i>	Duration: 90 minutes 1. Warm-up: short walk to the walking point (either a park or an area near the center) 2. Interval walking: every patient do interval walking with the InterWalk app for a minimum of 30 minutes. The health professionals guide and facilitate the walking. 3. Group conversation: takes place at the health promotion center after doing interval walking with all participation patients. Here different focus areas are discussed in the group. The health professional participates as a facilitators in the group conversation (examples of focus areas: weather conditions, motivation for exercise, social needs when waking, motivation for a physically active everyday life)

Experimental intervention, phase two

In phase two patients in the experimental intervention group are randomly allocated into two follow-up conditions: with unsupervised interval walking training without support (IWTgroup) or with motivational support (IWTsupport-group) following the intervention period until 52-week follow-up (see Figure 1).

Interval Walking Group without support (IWTgroup)

All patients in the Interval Walking Group (IWTgroup) are encouraged to continue to perform IWT with the InterWalk app three times a week, 30 to 60 minutes per session. The patients are not provided with any follow-up or support from health professionals from the end of the intervention period until follow-up at 52-weeks. However, patients are allowed to contact the health professionals at the health promotion centre at any time if necessary.

Interval Walking Group with support (IWTsupport-group)

Patients in the Interval Walking Group with support (IWTsupport-group) are also encouraged to do IWT with the InterWalk app three times per week. All patients in the IWTsupport-group receive additional motivational support by the health professionals at the promotion centre (see below for information regarding the motivational support).

Motivational support (phase two)

The motivational support is summarised in Table 4. The motivational intervention consists of four motivational interviews with individual goal setting and weekly Short Message

Service via the mobile phone (a SMS-track), (see Figure 5 and 6). Furthermore, patients have the opportunity to participate in IWT at predefined timeslots with an Interval Walking Ambassador in the local community near the health promotion centre (see Figure 1).

Motivational interview and goal setting: The Motivational interview is used to structure the communication between the patient and the health professional. The interview works as a partnership where focused and detailed questions reveal and visualize the patients motivation and barriers towards behaviour change and acknowledgement of patient autonomy.[26] Four motivational interviews are scheduled for each patient in the IWT support-group. See Table 4 for more detail. The interviews seek to help the patients reflect on their physically active habits and to set individual motivating goals related to everyday life.[27] The goal setting is based on the S.M.A.R.T.-principle derived from the Goal Setting Theory developed by Edwin Locke.[28] S stands for Specific (e.g. what do I want to accomplish?), M for Measurable (e.g. specific and measurable), A for achievable (realistic), R for relevant (individual goals) and T for timely (not too big to achieve in a short period).[29]

**Table 4. MOTIVATIONAL INTERVIEWS WITH INDIVIDUAL GOAL SETTING
PHASE TWO, IWTsupport-group**

<i>Four motivational interviews with individual goal setting,</i>	<p>The interviews aim at helping the patient to reflect on why and how physical activity can be incorporated in everyday life</p> <ul style="list-style-type: none"> ○ Make informed choices regarding behavioral changes regarding physical activity ○ Relate to own everyday life ○ Clarify barriers and facilitators of importance for the individual <p>Two to three individual goals are set at all interviews</p>
---	--

The goals is based on need in the individual everyday life

A short resume with the individual goal setting is written after all interviews in the database.

The written text is prospectively incorporated in the following interviews with the patient at the health promotion center

The interviews are placed in Week 16, 20, 28, 40 post baseline-test. Goal setting in the interviews are based on the *the S.M.A.R.T.- principle derived from the Goal Setting Theory developed by Edwin Locke*. [28]

Short Message Service (henceforth referred to as text message) enables inexpensive and possibly effective interaction between patients and health professionals at any time or place.[30,31] Communication as well as feedback is believed to enhance motivation through feelings of competence and relatedness [32], which may positively affect adherence to treatment. Text messages have shown positive effect on various health outcomes including diabetes self-management when used in behavior change interventions. Further, a higher effectiveness and lower attrition rate has been observed when customized and tailored messages is used.[30] In the present study, the patient receives two types of text messages during phase two (see Figure 4 and 5). The first type is a weekly and interactive text message consisting of questions regarding the amount of IWT performed during the past week (see Figure 4). The patients are required to give feedback by returning a text message with one of the three response options provided. If the patient does not reply for two consecutive weeks, or if the patient answers that she/he has not been walking, a personal phone call to the patient is conducted from a health professional from the local health promotion centre. The aim of the call is to encourage and help the patient to plan IWT to fit the individual life of the patient. The second type of text message is sent every fourth week,

20 *Interval Walking Ambassadors:* Using peers to educate other patients with
21 T2D has shown effective in providing ongoing support over a longer period.[33,34] In this
22 study, volunteer patients with T2D are recruited through the Danish Diabetes Association,
23 where a consultant contacts possible patients via e-mail. The Interval Walking Ambassadors
24 do IWT locally in phase two with patients from the IWTsupport group. The Interval
25 Walking Ambassadors receives a two-day training programme in the participating
26 municipality by researchers from the InterWalk research group. At any time during phase
27 two, patients can attend IWT at predefined timeslots with an Interval Walking Ambassador
28 (see Table 2).

phase until week 52. Patients in IWTgroup have no contact with the health professionals until 52-weeks follow-up (see Figure 1).

Control intervention – Standard care

Patients in the control group receive the standard rehabilitation treatment offered to patients with T2D in Denmark in a multimodal setting including physical activity (phase one, Figure 1). The duration of rehabilitation treatment differs between participating municipalities, but may not be shorter than eight weeks during phase one. At the end of the standard care rehabilitation program in the municipalities there is no follow-up on the exercise intervention, which is the normal procedure in Danish municipalities (phase two, Figure 1).[35]

The participating municipalities offer group exercise twice a week at the health promotion centres with 6-15 patients participating depending on the population size in the participating municipality. The content of the group exercise period is based on clinical guidelines in Denmark. A typical session is structured with first a short warm-up session followed by a strength and cardio part and finished with a cool-down period with strengthening (See Table 2). Furthermore, it is recommended that the patients have regularly consultation at the general practitioner every third month.

* Article 1: The effectiveness of smartphone delivered Interval Walking Training on moderate-and-vigorous physical activity versus standard care in patients with type 2 diabetes: a parallel group single-blinded randomized controlled trial.

†Article 2: Baseline characteristics and personality traits in patients with type 2 diabetes: descriptive study of all participants

‡Article 3: Nay Sayers – Characteristics of patients who does not want to be part of a physical activity study related to everyday life; all patients referred to the health promotion centers in the municipalities participating in the randomized controlled trial.

§Article 4: Effectiveness of smartphone delivered Interval Walking Training versus standard care in patients with type 2 diabetes on HbA1c and HDL, high-density lipoprotein; LDL, low-density lipoprotein: A sub-study to the randomized controlled trial (The InterWalk Trial, article 1), measured in a sub-sample (n=40).

Primary outcome

The primary outcome is change in moderate-to-vigorous-intensity physical activity from baseline to 52-week follow-up.

Secondary outcomes

The key secondary outcome changes in motivation for sustaining a behavioural change with physical activity in everyday life at 52-week follow-up.

Other secondary outcomes of interest are changes in patients' fitness level measured as VO₂-peak by the standardised walking test (part of the InterWalk application) and health-related quality of life. Strength in the lower extremities, adherence to intervention and impact of personality traits on physical activity in everyday life are also considered exploratory secondary outcomes. All outcomes are measured at baseline, after intervention and at 52-week follow-up (see Figure 2).

Data collection

Level of daily moderate-to-vigorous-intensity physical activity

It is important to gain knowledge into physical activity in everyday life. To determine level of daily moderate-to-vigorous-intensity physical activity a hip-mounted physical activity monitor (Axivity AX3, Newcastle, UK) is worn for seven consecutive days, at three time periods during the trial period; after baseline-test, after the intervention period and again at

52-weeks follow-up. The monitor is fixed using adhesive tape (Leukomed T, BSN medical, Germany) on right side the lumbar spine. Additionally, a monitor is fixed on on the lateral side of the right thigh (Leukomed T, BSN medical, Germany) for supporting information about posture.[25] The patients are instructed not to remove the physical activity monitor at any time during the three time periods. If de-attached, the participants are trained in fixing the monitors correctly and are instructed to note the incident. If the patients need help in fixing the monitors correctly the health professionals at the health promotion centre are educated to help.

Physical activity diary

In order to validate the physical activity level during the seven days with physical activity monitors we ask the patient to complete a seven-day diary to report number of work- and sleep hours, bicycling and strength training sessions at the three time periods on a daily basis. The physical activity monitor and the diary are returned free-of-charge via mail. The patient is contacted by phone after within one week if the physical activity monitors are not returned as expected.

Motivation for behaviour change with physical activity

Changes in motivation for sustaining a behavioural change with physical activity in everyday life is measured with the Behavioural Regulation of Exercise Questionnaire

1
2
3
4
5
6
7
8
9 (BREQ-2) which measures individual motivation for physical activity. The questionnaire
10 consists of 19 questions in a 0-4 Likert format.[36] In addition to the questionnaire, patients
11 are asked to answer four questions in a 0-4 Likert format, regarding motivation for physical
12 activity after being diagnosed with T2D.
13
14
15
16

17 18 19 20 *Health Related Quality of Life*

21 The patients Health Related Quality of Life is very important to maintain after being
22 diagnosed with T2D.[37] To gain knowledge into the individual perception of quality of life
23 on a physical and mental level we use the Short-Form Health Survey (SF-12). The
24 questionnaire consists of 12 questions and uses a Likert scale of 1-3 for the physical function
25 items; 1-5 for the bodily pain, social function, and general health perceptions items; 1-6 for
26 the vitality and mental health; and a dichotomous scale of yes/no for the presence of role
27 function limitations. The higher score, the higher level of health or functioning.[38]

30
31
32
33
34
35
36
37
38
39

40 *Maintenance of behaviour change with physical activity*

41 Automaticity of behaviour is essential when new habits become present in the everyday
42 life.[39] To measure if the patient has adopted new habits as a result of the intervention we
43 ask the patient to answer four questions from The Self-Report Habit Index. The Index uses a
44 0-4 Likert format and the four questions to be answered measures automatic activation,
45 frequency of behaviour and relevance to self-identity related to physical activity.[40]

58
59
60

VO₂-peak

Incorporated in the InterWalk app is a standardised walking test consisting of 5 stages; 1) 30 sec. of standing still, 2) 2 min. of slow walking 3) 2 min. of walking at moderate intensity 4) 2 min. walking at high intensity 5) 1 min. walking at highest intensity possible. The four paces are self-selected (See, Figure 3 and 4). The test is performed with an iPod placed in the pocket at the hip and the instructions are delivered from the app through earphones. To ensure the right walking intensity in the intervention period, the patients are asked to perform the test every 4th week.[16]

Strength in the lower extremities

The sit-to-stand test (30 seconds) measures the lower body strength and will be administered using a chair without arms. The patient is encouraged to complete as many full stands as possible within a 30-sec time limit.[41]

Adherence to the intervention

Adherence is determined by an evaluation and quantification of the electronic log of data from the InterWalk app to the central database of all uploaded data.

Self-rated physical activity

1
2
3
4
5
6
7
8
9 The “Recent Physical Activity Questionnaire” (RPAQ) has 9 main questions, which covers
10 4 domains of physical activity: domestic life, work, recreation and transport. Physical
11 Activity is estimated in MET’s (Metabolic Equivalent). In answering the questions in the
12 questionnaire, the patient will answer in regards to the last four weeks with physical activity
13 in the everyday life.[42]
14
15
16
17
18
19

20 21 22 *Personality traits*

23
24 The NEO-Five Factor Inventory (NEO-FFI) [43] consists of 60 questions in a 0-4 Likert
25 format constructed by selecting 2 items from each of the six facets characterizing each of the
26 five personality traits (Neuroticism, Extraversion, Openness, Agreeableness,
27 Conscientiousness) assessed by NEO-PI-R. The Sensation Seeking Scale (SES) [44] is a 40
28 items self-administered questionnaire consisting of 40 questions designed to test the
29 tendency towards varied, novel and intense sensations.

Height measurement is conducted using a portable altimeter (Tanita Stadiometer). The measurement is done without shoes and is repeated two times with each measure to nearest 0,1 cm. If the two measures are dissimilar with more than 0,5 cm, then the measurement is repeated. *Weigh* is measured in kilograms (kg) using an electronic weight. The measure is repeated two times with each measure to nearest 0,1 cm. If the two measures are dissimilar with more than 0,5 kg, then the measurement is repeated a third time. The patient is weighed fully dressed and one kilo is subtracted from each measure. *Hip circumference* is measured on the skin on the crest of the hipbone. The patient is asked to place a finger in the belly bottom and the measure is done with a tape measure (2 meters) placed on the upper side of the patients' finger. If the two measures are dissimilar with more than 0,5 cm, then the measurement is repeated a third time.

Safety criteria and adverse events

Patients are informed that performing the InterWalk walking test may cause some degree of breathlessness as patients are expected to reach 80-85% of VO_2 max during the walking test. All other measurements are not associated with any known risk or discomfort. Injuries linked to the intervention are registered, if informed to the health professionals at the health promotion centres, during the trial period. In case of severe adverse events, the Scientific Ethical Committee of the Capital Region of Denmark is informed.

Sample size considerations

The minimum difference of interest (MDI) is 10 minutes per day. Based on existing experimental evidence, we expect the standard deviation (SD) of the change in moderate-and-vigorous physical activity from baseline to 12 month follow up to be between 1.2 – 2.3 times the effect size.[45,46] Therefore, SD twice the MDI (20 min of moderate-and-vigorous physical activity) per day was applied in the sample size calculations. After applying Bonferroni adjustment due to multiple comparisons in the three group trial a total of 190 participants are needed to obtain a statistical power (1- β) of 80% with an α of 0.017 (two-tailed). Allowing for an attrition rate of 30%, 272 patients (91 in the control group and 181 in experimental group) are recruited. The setting enables recruitment until December 15st 2016. The sample size is truncated at 272 participants or the N reached at the end of recruitment period - whatever is reached first (see section ‘Participants’).

Randomisation, sequence generation and allocation concealment

After returning the physical activity monitors patients are randomised to either standard care or experimental group after baseline test (phase one). Allocation to either IWTgroup or IWTsupport-group on patients allocated to the experimental group is concealed until after the post intervention test (phase two). A health professional associated with the trial, telephones the patient and inform about random allocation after returning the PA monitors to either IWT-group or IWTsupport-group. The patients are stratified by gender to ensure an

1
2
3
4
5
6
7
8
9 equal number across all groups. The allocation sequence is generated through a standardised
10 computer program by an independent researcher (RC). The allocation sequence is concealed
11 until the trial arms are assigned. A Flow of patients is depicted in Figure 2.
12
13

14 15 16 17 **Blinding**

18 The scientific staff is blinded to patient allocation from baseline to the 52-week follow-up is
19 completed for all patients. The health professionals at the promotion centre are not blinded
20 to allocation to either standard care or experimental groups.
21
22
23
24

25 26 27 28 **Statistical methods**

29 All analyses will be conducted according to the Intention-To-Treat principle. Continuous
30 endpoints will be analysed using repeated measures analysis of covariance in a mixed
31 linear model. Categorical and dichotomous end points will be analysed with the use of
32 logistic regression. The model will include with group, and sex as fixed effects, with the
33 baseline value as a covariate.
34
35
36
37
38
39

40
41 All patients randomised to one treatment, will be analysed according to the
42 treatment to which the patient was allocated, irrespective of whether they received this or
43 some other treatment, or no treatment at all. The ITT population will be handled all patients
44 randomised to the three treatment arms, and the dataset is equal to the “all patients
45 randomized set” (APRS). Missing values due to patients’ absence from follow-ups or
46 withdrawal from the study are to be expected in clinical trials. Several approaches are
47
48
49
50
51
52
53
54
55
56
57
58
59
60

described for handling missing data in the ITT analysis, and among them “baseline observation carried forward” (BOCF: i.e., a null-responder imputation, where the level at baseline is also considered the last). A linear mixed model analysis includes all patients with a baseline assessment, and includes both fixed and random factors. Thus, repeated linear mixed model method is chosen for the primary analyses in this trial (i.e., no data imputation), whereas the BOCF imputation, as well as the ‘Per Protocol’ population will be applied for the purpose of sensitivity analysis. Exploratory analyses of the treatment effects will be performed on the secondary outcomes.

Data management and quality control

All data are entered in an SSL-secured, online-based database developed by the Danish Stakeholder Help2Run (CVR: 34801088). The online-based database logistically handles the data gathered at baseline, after intervention in phase one, and during follow-up (phase two) and after 52 weeks. Data on demography, measurements, tests and questionnaires are entered directly in the database available via a project-specific homepage (<http://www.runsafe.dk/mtd/login/admin-signi><https://www.runsafe.dk/mtd/login/admin-signin>). A protected back-end system (<https://www.runsafe.dk/mtd/admin>) is used to logistically handle information on demography, measurements, tests and questionnaires on each participant in the trial (for information on interval walking training using the InterWalk app see ‘*Interval Walking*

1
2
3
4
5
6
7
8
9 *Training using The InterWalk Application*’). The system was approved in 2014 after an
10 inspection by the Danish Data Protection Agency. Access to personalized data from
11 the InterWalk participants is only possible using a personalized username and password.
12 Only specified researchers are allowed to administrate the back-end system and each
13 researcher and project member with access to the back-end has a unique username and
14 personal password for the back-end system. All activities, including changing data and
15 downloading data, in the back-end system are logged in accordance with the rules and
16 regulations from the Danish Data Protection Agency. A unique subject ID number will be
17 subscribed to all patients in order to anonymize data. The identification key (ID to personal
18 information) will be encrypted and stored securely and separately from the unique ID
19 number on a secure database.

34

35 ***Ethics and Dissemination***

36
37 The InterWalk trial contributes with important knowledge on different treatment approaches
38 in the rehabilitation of patients with T2D. Physical activity and exercise have beneficial
39 effect on patients with T2D when the interventions are conducted in well-designed efficacy
40 studies.[2,4,6] However, little is known on whether this effect also is present in effectiveness
41 studies or “real-world setting” studies. These studies are of great importance and relevance
42 regarding evidence-based medicine highlighting the importance of the InterWalk trial.
43
44
45
46
47
48
49

50 The InterWalk trial has a pragmatic design that allows for different
51 intervention periods in the participating municipalities. Furthermore, the interventions are
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 conducted directly in the clinical setting giving a more reliable frame of the experienced
10 challenges in a population with T2D. We believe that the implementation of the study results
11 will have a smoother implementation phase, as the health professionals already are familiar
12 with the preceding's.
13

14
15
16
17
18 The trial gives valuable insight into the impact of different motivational and
19 supportive tools as well as knowledge about individual motivation and the impact on
20 sustaining a newly acquired behaviour change regarding physical activity in everyday life.
21
22

23
24 Interval Walking Training is expected to be a suitable and effective way of
25 providing moderate-vigorous physical activity for at large group of patients with T2D. IWT
26 can be done at any time and anywhere and is thus integrated and tailored to fit individual
27 everyday life. The overall objective is to promote lifelong physical activity for the individual
28 and we believe that experiences from the present trial can help when planning future
29 interventions with IWT to patients with various lifestyle diseases e.g. coronary heart
30 diseases.
31
32
33
34
35
36
37
38

39
40 It is a major advantage that the trial is designed as a randomised controlled trial
41 in a “real-world setting” with a study population representing patients with T2D referred to
42 rehabilitation. Furthermore, data and results are collected consecutively and directly in the
43 clinical setting in which the interventions are to be used after the trial. Together with the
44 very limited number of inclusion and exclusion criteria and a stratification of patients on
45
46

Effect of Interval walking on type 2 diabetics

BMJ Open

1
2
3
4
5
6
7
8
9 gender secures external validity of the trial and thus will add important information to the
10 current body of evidence on T2D treatment.

11
12 All data from eHealth solutions as the InterWalk app are electronically
13 monitored. The patient is not dependent on opening hours at the health promotion centre as
14 the InterWalk is either installed on an iPhone or an iPod. This gives a unique possibility for
15 the patient to be physically active whenever it fits in their everyday life.
16
17
18
19
20
21

22 We acknowledge that physical activity only has effect when adherence is
23 high, which is why we first compare standard care with interval walking for a shorter
24 period (phase one) followed by a re-allocation of patients in the experimental group to
25 either interval walking with or without motivational support (phase two). All groups have a
26 52-week follow-up. The trial design enables us to investigate if patients are able to
27 maintain a newly acquired behaviour change with physical activity in everyday life with or
28 without motivational support for a longer period.
29
30
31
32
33
34
35
36

37 All personalized data and measures are stored on a central online-based
38 database developed to logistically handle all data collected at baseline and during follow-
39 up. The backend system (<https://www.runsafe.dk/mtd/admin/>) secures all information
40 from each patient. The construction of the database with personalized usernames,
41 passwords, and specific permissions to all health professionals and administering
42 permissions to scientific staff in the backend secures all data. Furthermore, all activities are
43 logged.
44
45
46
47
48

56
57
58
59
60

1
2
3
4
5
6
7
8
9 All outcomes measures are assessed blinded to allocation at baseline and the
10 primary outcome is assessed blinded to intervention in the experimental group after the
11 intervention period. All measures are conducted by the health professionals at the health
12 promotion centres and are blinded for allocation after intervention in the experimental group
13 with IWT until after return of the physical activity monitors by the patient. All statistical
14 analyses are blinded to researchers, reducing the risk of detection and interpretation
15 bias.[47–49] All secondary outcomes, but VO₂-peak and the Sit to Stand Test are self-
16 reported and by nature likely to be biased. The patients answer questionnaires independently
17 of the health professionals at the health promotion centres.
18
19
20
21
22
23
24
25
26
27

28 The secondary outcomes of motivation for physical activity and behaviour
29 change are of highly importance as knowledge concerning motivational support and
30 maintenance of effect (new habits with physical activity) to our knowledge is lacking in
31 patients with T2D. This knowledge will help health professionals to better tailor the
32 treatment and hereby potentially achieve a higher adherence to the programme following the
33 supervised intervention.
34
35
36
37
38
39
40
41

42 The limitations in this trial are similar to those of other exercise trials where
43 physical testing and time-of-day and day-to-day variation constitute a challenge. We have
44 standardised all testing protocols for all procedures to reduce the variation and run a
45 routine program of on-going calibration and training of the health professionals.

The trial is conducted in accordance with the Helsinki Declaration II.[50] All eligible patients receive written and oral informed consent prior to inclusion before any additional trial procedures. Data on all screened patients are registered in order to report characteristics of in-eligible patients and written informed consent is also obtained from these patients. The patients can withdraw from the trial at all times during the trial period. This has no consequence for any other future treatment. If patients discontinue the trial intervention, standard care is offered for the rest of the intervention period. All results from the trial, negative, positive or inconclusive results, are disseminated in international peer-reviewed scientific papers and at national and international conferences. We follow the guidelines from the International Committee of Medical Journal Editors when authorship is determined. The results will be reported when all long-term data become accessible.

33
34
35
36
37
38
39
40
41

Furthermore, all results are shared with the participating municipalities and participating health professionals and are used to develop future intervention and implementation strategies in the Danish municipalities.

carefully monitored every week by the research team. In July 2016, 210 patients had been enrolled in the trial.

Contributors LSV, MR-L and HL drafted the manuscript. All authors made substantial contributions to conception and design, and revised the manuscripts critically for important intellectual content. All authors have given their approval for the manuscript to be published.

Funding. The work has been supported by two grants by the Tryg Foundation, Denmark. The Centre for Physical Activity Research (CFAS) is supported by a grant from TrygFonden. The study was further supported by grants from. The Augustinus Foundation and two Foundations in the Capital Region of Denmark – the Foundation for Prevention and the Foundation for Intersectorial Research Projects have also supported the work.

Laura Staun Valentiner is supported by a grant from the Municipality of Copenhagen, Denmark and The Danish Physiotherapist Foundation. Mathias Ried-Larsen is supported by a post-doctoral grant from the Danish Diabetes Academy supported by the Novo Nordisk Foundation and The Vissing Foundation. CIM/CFAS is a member of DD2 - the Danish Center for Strategic Research in Type 2 Diabetes (the Danish Council for Strategic Research, grant no. 09-067009 and 09-075724). SPIRIT 2013 Checklist: Recommended items to address in a clinical trial protocol and related documents*

Section/Item	ItemNo	Description	Page
Administrative information			
Title	1	Descriptive title identifying the study design, population, interventions, and, if applicable, trial acronym	1
Trial registration	2a	Trial identifier and registry name. If not yet registered, name of intended registry	2 & 5
	2b	All items from the World Health Organization Trial Registration Data Set	4, 31, 1, 5, 7-22, 6, 26, 23
Protocol version	3	Date and version identifier	N/A
Funding	4	Sources and types of financial, material, and other support	33
Roles and responsibilities	5a	Names, affiliations, and roles of protocol contributors	33
	5b	Name and contact information for the trial sponsor	N/A
	5c	Role of study sponsor and funders, if any, in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication, including whether they will have ultimate authority over any of these activities	N/A
	5d	Composition, roles, and responsibilities of the coordinating centre, steering committee, endpoint adjudication committee, data management team, and other individuals or groups overseeing the trial, if applicable (see Item 21a for data monitoring committee)	7, 16, 17, 31
Introduction			
Background and rationale	6a	Description of research question and justification for undertaking the trial, including summary of relevant studies (published and unpublished) examining benefits and harms for each intervention	3, 7-22
	6b	Explanation for choice of comparators	4, 16, 29
Objectives	7	Specific objectives or hypotheses	4
Trial design	8	Description of trial design including type of trial (eg, parallel group, crossover, factorial, single group), allocation ratio, and framework (eg, superiority, equivalence, noninferiority, exploratory)	4
Methods: Participants, interventions, and outcomes			
Study setting	9	Description of study settings (eg, community clinic, academic hospital) and list of countries where data will be collected. Reference to where list of study sites can be obtained	4
Eligibility criteria	10	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will perform the interventions (eg, surgeons, psychotherapists)	5, 6

Interventions	11a	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	5-22
	11b	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving/worsening disease)	14, 21
	11c	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return, laboratory tests)	12, 14
	11d	Relevant concomitant care and interventions that are permitted or prohibited during the trial	14
Outcomes	12	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	23
Participant timeline	13	Time schedule of enrolment, interventions (including any run-ins and washouts), assessments, and visits for participants. A schematic diagram is highly recommended (see Figure)	5, 24, 27
Sample size	14	Estimated number of participants needed to achieve study objectives and how it was determined, including clinical and statistical assumptions supporting any sample size calculations	25
Recruitment	15	Strategies for achieving adequate participant enrolment to reach target sample size	4

Methods: Assignment of interventions (for controlled trials)

Allocation:

Sequence generation	16a	Method of generating the allocation sequence (eg, computer-generated random numbers), and list of any factors for stratification. To reduce predictability of a random sequence, details of any planned restriction (eg, blocking) should be provided in a separate document that is unavailable to those who enrol participants or assign interventions	27
Allocation concealment mechanism	16b	Mechanism of implementing the allocation sequence (eg, central telephone; sequentially numbered, opaque, sealed envelopes), describing any steps to conceal the sequence until interventions are assigned	27
Implementation	16c	Who will generate the allocation sequence, who will enrol participants, and who will assign participants to interventions	27
Blinding (masking)	17a	Who will be blinded after assignment to interventions (eg, trial participants, care providers, outcome assessors, data analysts), and how	28
	17b	If blinded, circumstances under which unblinding is permissible, and procedure for revealing a participant's allocated intervention during the trial	21

Methods: Data collection, management, and analysis

1				
2	Data collection methods	18a	Plans for assessment and collection of outcome, baseline, and other trial data, including any related processes to promote data quality (eg, duplicate measurements, training of assessors) and a description of study instruments (eg, questionnaires, laboratory tests) along with their reliability and validity, if known. Reference to where data collection forms can be found, if not in the protocol	24
3				
4				
5				
6				
7				
8		18b	Plans to promote participant retention and complete follow-up, including list of any outcome data to be collected for participants who discontinue or deviate from intervention protocols	22
9				
10				
11	Data management	19	Plans for data entry, coding, security, and storage, including any related processes to promote data quality (eg, double data entry; range checks for data values). Reference to where details of data management procedures can be found, if not in the protocol	31
12				
13				
14				
15				
16	Statistical methods	20a	Statistical methods for analysing primary and secondary outcomes. Reference to where other details of the statistical analysis plan can be found, if not in the protocol	28
17				
18				
19		20b	Methods for any additional analyses (eg, subgroup and adjusted analyses)	N/A
20				
21		20c	Definition of analysis population relating to protocol non-adherence (eg, as randomised analysis), and any statistical methods to handle missing data (eg, multiple imputation)	N/A
22				
23				
24	Methods: Monitoring			
25				
26	Data monitoring	21a	Composition of data monitoring committee (DMC); summary of its role and reporting structure; statement of whether it is independent from the sponsor and competing interests; and reference to where further details about its charter can be found, if not in the protocol. Alternatively, an explanation of why a DMC is not needed	31
27				
28				
29				
30				
31		21b	Description of any interim analyses and stopping guidelines, including who will have access to these interim results and make the final decision to terminate the trial	N/A
32				
33				
34	Harms	22	Plans for collecting, assessing, reporting, and managing solicited and spontaneously reported adverse events and other unintended effects of trial interventions or trial conduct	21, 31
35				
36				
37				
38	Auditing	23	Frequency and procedures for auditing trial conduct, if any, and whether the process will be independent from investigators and the sponsor	N/A
39				
40				
41	Ethics and dissemination			
42				
43	Research ethics approval	24	Plans for seeking research ethics committee/institutional review board (REC/IRB) approval	5
44				
45	Protocol amendments	25	Plans for communicating important protocol modifications (eg, changes to eligibility criteria, outcomes, analyses) to relevant parties (eg, investigators, REC/IRBs, trial participants, trial registries, journals, regulators)	5
46				
47				
48				
49	Consent or assent	26a	Who will obtain informed consent or assent from potential trial participants or authorised surrogates, and how (see Item 32)	5
50				
51				
52		26b	Additional consent provisions for collection and use of participant data and biological specimens in ancillary studies, if applicable	32
53				
54				
55	Confidentiality	27	How personal information about potential and enrolled participants will be collected, shared, and maintained in order to protect confidentiality before, during, and after the trial	31
56				
57				
58				
59				
60				

1				
2	Declaration of interests	28	Financial and other competing interests for principal investigators for the overall trial and each study site	33
3				
4	Access to data	29	Statement of who will have access to the final trial dataset, and disclosure of contractual agreements that limit such access for investigators	31
5				
6	Ancillary and post-trial care	30	Provisions, if any, for ancillary and post-trial care, and for compensation to those who suffer harm from trial participation	N/A
7				
8	Dissemination policy	31a	Plans for investigators and sponsor to communicate trial results to participants, healthcare professionals, the public, and other relevant groups (eg, via publication, reporting in results databases, or other data sharing arrangements), including any publication restrictions	31
9				
10		31b	Authorship eligibility guidelines and any intended use of professional writers	31
11				
12		31c	Plans, if any, for granting public access to the full protocol, participant-level dataset, and statistical code	N/A
13				
14				
15				
16				
17				
18				
19				
20	Appendices			
21				
22	Informed consent materials	32	Model consent form and other related documentation given to participants and authorised surrogates	N/A
23				
24				
25	Biological specimens	33	Plans for collection, laboratory evaluation, and storage of biological specimens for genetic or molecular analysis in the current trial and for future use in ancillary studies, if applicable	32
26				
27				

*It is strongly recommended that this checklist be read in conjunction with the SPIRIT 2013 Explanation & Elaboration for important clarification on the items. Amendments to the protocol should be tracked and dated. ABSTRACT:**Introduction**

Physical activity is a cornerstone in Type 2 diabetes (T2D) rehabilitation. Effective long-term and low-cost strategies to keep these patients' physically active are needed. However, maintaining physical activity behaviour is difficult once formalised interventions end. Structured exercise training supported by mobile technology and remote feedback is potentially an effective strategy.

The objective of the trial is to investigate whether mobile health support using the InterWalk application for smartphones is effective in increasing physical activity levels in persons with T2D over time compared to standard care.

We investigate whether Interval Walking Training (IWT) using the InterWalk application is superior to Danish municipality-based rehabilitation in increasing moderate-and-vigorous physical activity levels in patients with T2D across 52 weeks. Secondary, we hypothesize that a motivational programme added from end of intervention to 52-weeks further increases level of physical activity in everyday life in patients with T2D.

Methods and analysis

The trial is a parallel-group, open-labelled, randomised controlled trial with long-term follow-up at 52-week including patients with T2D. The primary outcome is change in moderate-and-vigorous physical activity. The key secondary outcome includes motivation for physical activity behaviour change. Other secondary outcomes are VO_2 -peak, strength in

1
2
3
4
5
6
7
8
9 the lower extremities. Exclusion criterion is medical contraindication to exercise. We
10 include up to 246 patients and randomly allocate them into a control (standard group) or an
11 experimental group (8-12 weeks of IWT supported by the smartphone-based InterWalk
12 application) in a 1:2 fashion. After intervention, the experimental group is randomly
13 allocated into two follow-up conditions with unsupervised IWT with or without motivational
14 support until 52-week follow-up. The Intention-To-Treat principle is applied.

40 **STRENGTHS:**

- 41 ○ The trial is the largest of its kind, and meets the criteria for high quality randomized
42 controlled trials with central randomization and use of valid and reliable measures.
43
- 44 ○ The efficiency of Interval Walking Training on e.g. glycaemic control has
45 previously been demonstrated.
46
- 47 ○ The trial has a long-term follow-up period of 52-weeks from baseline.

Effect of Interval walking on type 2 diabetics

BMJ Open

- The trial has high external validity with relevance for the clinical setting as it is performed within clinical practice and includes a limited use of inclusion/exclusion criteria's.

LIMITS:

- The trial has several collaborators in the setup which may cause variation in the testing procedures.
- Lack of clinical endpoints e.g. depression and mental health
- The length of the intervention periods varies between the three collaborating municipalities may influence the results of the trial.
- There may be a risk of contamination in the control group as the InterWalk application can be downloaded in App Store.

INTRODUCTION

Physical activity (PA) is a cornerstone in the clinical care of patients with type 2 diabetes (T2D).[1] PA activity has beneficial effect on glycaemic control and other key metabolic risk factors [2,3], as well as improvements in quality of life.[4,5] Furthermore, supervised long-term PA interventions have proven effective in improving glycaemic control.[2,6] However, experimental evidence does not support the efficiency of advice about physical activity alone.[7] As the number of patients with T2D is estimated to rise to 500 million by 2030 worldwide [8,9] the implementation of structured, long-term and supervised exercise regimes constitutes a large societal challenge and is not feasible. Thus, novel strategies to increase physical activity among patients with T2D are needed.

Smartphones have been used as a tool to register exercise, diet, weight and plasma glucose levels, but the evidence for using a smartphone as an exercise device and a self-management tool in the diabetes care is lacking.[10] However, emerging evidence suggest that eHealth solutions using information and communication technologies [11] can educate and engage patients with T2D in long-term self-management.[12–14] Due to the large ingress and ownership of smartphones, a smartphone-supported approach could prove feasible in increasing physical activity among patients with T2D and accommodate the increasing prevalence of T2D.

Efficiency of Interval Walking Training (IWT) in patients with T2D has been established.[15] In the study by Karstoft and co-workers, IWT was administered and

1
2
3
4
5
6
7
8
9 monitored using a small exercise computer (JD-mate). IWT induced significant improvements
10 in physical fitness level, body composition and glycaemic control and in adherence of more
11 than 85% over a 16 weeks period.[15] The potential benefits of implementing eHealth
12 solutions in T2D management and the apparent health benefits of and adherence to IWT gave
13 rise to the development of the InterWalk application (InterWalk app) to deliver IWT.[16]
14
15

17
18

19
20 There is a lack of knowledge about the integration of PA in the everyday life
21 of the patient following rehabilitation interventions.[17] It is, however, known that
22 successful behavioural change depends on an on-going maintenance of individual
23 motivation regarding the behaviour and behavioural change itself.[18] Furthermore, time
24 since onset of diagnosis, unhealthy behaviour and own beliefs about the cause of the
25 problem, together with the number of previous attempts to change and support from
26 partners, peers and health professionals are of relevance.[18] This underlines the need for
27 new interventions with a direct focus on motivational support and self-control regarding
28 sustaining a newly acquired behavioural change with PA. To better target and structure
29 manageable interventions related to patients with T2D, understanding patients' individual
30 priorities and values are crucial. In this regard, knowledge of individual motivation and self-
31 efficacy to initiate behavioural changes becomes essential to understand.[18]

13 14 15 **Trial objective and hypothesis** 16

17 The objective of the trial is to investigate whether mobile support using the InterWalk
18 application for smartphones is effective in increasing physical activity levels in persons with
19 type 2 diabetes over time compared with a standard care rehabilitation program.
20
21
22

23 We investigate the effectiveness of the implementation of Interval Walking Training using the
24 InterWalk application in the Danish municipality-based rehabilitation program and study
25 whether the Interval Walking Training is superior to standard care in increasing moderate-
26 vigorous physical activity 52 after weeks. Furthermore, we expect that a motivational support
27 program added from end of the intervention to 52-weeks, will increase the physical activity
28 level in patients with type 2 diabetes and help maintaining a physically active everyday life
29 long-term.

42 **METHODS AND ANALYSIS** 43

44 ***Trial design and setting*** 45

46 The trial is a 52-week parallel-arm, open-labelled, randomised controlled trial. The
47 participants are randomly allocated into two groups, 1) standard care or 2) experimental
48 group with moderate-and-vigorous physical activity level, doing interval walking

facilitated by the InterWalk app. After an 8-12-week intervention period, patients in the experimental group are allocated to do interval walking using the InterWalk app with or without motivational support provided by the health professionals (see Figure 1).

[INSERT FIGURE 1 ABOUT HERE]

The intervention is conducted at the health promotion centres in Danish municipalities and hospitals that consecutively are included as cooperation partners. The municipality of Copenhagen is the first collaborator in the trial. Patients are referred to rehabilitation by their general practitioner (GP). Trained health professionals (physical therapists, nurses and staff with a master's degree) working at the health promotion centres recruit the patients, deliver the interventions and conduct all testing. The overall organization of health care in Denmark is fully tax-financed with universal access to health care services. The Danish model is described in detail elsewhere [21,22] and chronic disease care (including T2D) management is in Denmark based in the Chronic Care Model.[23]

Briefly, GPs refer patients diagnosed with T2D to rehabilitation at either an out-patient clinic, within a municipality or at the hospital level in Denmark. The setting depends on stage of the disease, presence of complications and co-morbidities e.g. severe heart conditions, depression or mental illness. The municipality based rehabilitation primarily includes non-complicated patients (~80% of all patients).[21] If complications or

1
2
3
4
5
6
7
8
9 co-morbidities are present, patients are referred to treatment at a specialized clinic at a
10 hospital. Patients with a non-complicated course of disease receive rehabilitation
11 consisting of: 1) disease-specific patient education, 2) diet counseling, 3) smoking
12 cessation and 4) exercise. The composition of the individual rehabilitation program
13 depends however on disease progression and on the rehabilitation offered in the
14 municipality-based program or at the hospital. The general focus is patient empowerment,
15 disease-related self-care and prevention of a decay of the functional capacity of patients
16 with T2D.

26 The Scientific Ethical Committee at the Capital Region of Denmark (H-1-
27 2014-074), and the Danish Data Protection Agency (j.nr. 2014-54-0897) have approved the
28 trial. The InterWalk application is approved by the Danish Data Protection Agency (2008-
29 58-0035). The trial has been registered at <http://www.clinicaltrials.org> (NCT02341690) on
30 January 9th, 2015. Amendments to the protocol will be approved by the Scientific Ethical
31 Committee at the Capital Region of Denmark. Amendments will be reported to
32 <http://www.clinicaltrials.org>. The trial is conducted in accordance with the Helsinki
33 Declaration.

All non-complicated patients diagnosed with T2D (out-patients), referred to a health promotion centre or hospital in the participating municipalities by their GP, are eligible if more than 18 years of age. A flow chart of participants is presented in Figure 2.

[INSERT FIGURE 2 ABOUT HERE]

The exclusion criteria are medical contraindications to exercise e.g. chronic complications in the locomotive apparatus, painful osteoarthritis or heart conditions.[24] Information is collected through medical records and at a screening interview with a health professional at the health promotion centre. Furthermore, patients are excluded if they do not want to be physically active in the rehabilitation setting or are already participating in other intervention studies at a health promotion centre. The patients have to be able to talk, read and understand the Danish language (for overview over in- and exclusion criterion, see Table 1).

If eligible, health professionals give oral and formalized written information with two days to consider participation in the trial. Written informed consent is obtained before any additional trial procedures. Enrolment was initiated in January 2015 and recruitment is terminated on December 15th 2016. Last-patient-last-visit is expected in December 2017.

Interventions

The trial is developed in collaboration with the health professionals from the municipality of Copenhagen in Denmark. The interventions are designed to reflect the clinical rehabilitation settings in Denmark in order to increase the likelihood of implementation of the programme following this trial, if proven superior. Health professionals from the municipalities already providing the rehabilitation delivers all interventions in both the control and experimental groups during the trial period. The investigators (LSV, CB and HL) led four workshops (16 hours in total) with the health professionals during year 2014, in which the interventions of the study and work routines were discussed in detail. Furthermore, all participating health professionals underwent a thorough education program (15 hours in total) involving all procedures and manuals in the trial. This was done to ensure standardization of all procedures throughout the trial. In addition, workshops were held from the start of the trial (January 2014) and hereafter every second month. This is done to secure that the health professionals follow all procedures and prepared manuals throughout the trial. The applicability of the trial results is hereby

1
2
3
4
5
6
7
8
9 increased, as the interventions are already part of the rehabilitation programme offered to
10 patients with T2D in the municipalities.
11

12
13 The interventions in the trial consist of two phases (Figure 1). In phase one (8-
14 12 weeks), patients are randomised to either a standard care group (control intervention) or
15 an experimental group doing IWT using the InterWalk app. The present trial uses the
16 standard care programme as control intervention and is conducted directly in the clinical
17 setting. All patients receive supervision across phase one. In phase two (40-44 weeks),
18 patients in the standard care group have no follow-up until 52 weeks post baseline. Patients
19 in the experimental intervention group are in phase two randomly allocated to either IWT
20 with or without motivational support (see section Experimental intervention – Interval
21 Walking with the InterWalk application). Additional rehabilitation care (co-interventions)
22 with disease-specific patient education, diet counseling and smoking cessation is offered to
23 all patients across the intervention groups. The interventions are summarized in Table 2.

Experimental intervention – Interval Walking Training with the InterWalk application

Patients allocated to the experimental intervention do interval walking after baseline test provided by health professionals (phase one). IWT is provided by health professionals to smaller groups of 3-12 patients. After the intervention period in phase two patients are allocated to either receive IWT without motivational support during follow-up (IWTgroup) or IWT with motivational support during follow-up (IWTsupport-group) (Figure 1). Trained health professionals conduct the IWT sessions (see below) and the motivational support in phase two. Table 2 gives an example of a typical week with interval walking in the experimental intervention group.

Interval Walking Training using The InterWalk Application

Interval Walking Training is performed using the InterWalk app, which works as a personal trainer as well as a monitoring unit allowing researchers to continuously and automatically monitor and store the physical activity level in a central database (Figure 3).[16]

Interval Walking Training is personalized through a standardised eight-minute walking test, performed with the app before engaging in IWT.[25] The InterWalk app guides the user in IWT with repeated cycles of 3 minutes fast and 3 minutes slow walking. During Interval Walking Training (IWT) the InterWalk app provides the patient with continuous feedback on the walking speed. The patients are able to track exercise history and receive historic feedback on the quality of the IWT session using the app. The feedback system

1
2
3
4
5
6
7
8
9 employs the on-board accelerometer of the phone and GPS system to assess intensity and
10 geographical location. Information on training intensity, total number of steps per day, IWT-
11 data and data from the standardised walking test is stored in the smartphone or iPod and
12 automatically transmitted to the central database at the Danish Strategic Research Centre for
13 Type 2 Diabetes (DD2) when connected to Wi-Fi or mobile data network.[16]

26 *Experimental intervention, phase one*

27
28 The patient receives a thorough introduction to the InterWalk app with follow-up
29 instructions. The introduction consists of information and test of the app and the patient can
30 ask clarifying questions if needed. A detailed manual regarding the InterWalk app is
31 extradited to each patient. The health professional provides technical guidance and helps the
32 patient to structure an everyday life with IWT during phase one. Patients are encouraged to
33 perform IWT using the InterWalk app (see section: InterWalk Walking Training using the
34 InterWalk Application) as a minimum three times per week, 30 to 60 minutes per session,
35 with two of the sessions taking place at the health promotion centre and the third is
36 conducted in the patient's everyday life environment. The aim is that all patients are capable
37 of continuing IWT using the InterWalk app at the end of phase one (Table 3).

Table 3, EXAMPLE OF EXPERIMENTAL INTERVENTION FOR ONE WEEK IN PHASE ONE

Weekday	Intervention at the Health promotion centre	Independent training in own environment	Notes to health professionals
<i>Monday</i>	Duration: 90 minutes 1. Warm-up: short walk in a group to the walking point (either a park or an area near the health promotion centre) 2. Interval Walking Training: every patient does Interval Walking Training with the InterWalk app for a minimum of 30 minutes. Every patient does the Interval Walking Training by themselves so that the app instructions during the session can be followed. The health professionals guide and facilitate the individual patient if necessary. After the Interval Walking Training everyone goes back to the health promotion centre 3. Group conversation at the health promotion centre after doing interval walking with all participating patients. Different focus areas are discussed in the group. Everyone sits on a chair and the health professional participates as a facilitators in the group conversation (examples of focus areas: weather conditions, motivation for exercise, social needs when waking, motivation for a physically active everyday life)		Remember to encourage and guide every patient to do Interval Walking Training three times a week either by themselves or together with other patients. Make sure that everyone are active during the walking sessions. If a patient needs to do a new walking test then it is the health professional who should help during the intervention period. Every patient need a new test every forth week.
<i>Tuesday</i>	Rest day		
<i>Wednesday</i>	Duration: 90 minutes 1. Warm-up: short walk in a group to the walking point (either a park or an area near the health promotion centre) 2. Experimental intervention, phase two

In phase two patients in the experimental intervention group are randomly allocated into two follow-up conditions: with unsupervised Interval Walking Training without support (IWTgroup) or with motivational support (IWTsupport-group) following the intervention period until 52-week follow-up (see Figure 1).

Interval Walking Group without support (IWTgroup)

All patients in the Interval Walking Group (IWTgroup) are encouraged to continue to perform IWT with the InterWalk app three times a week, 30 to 60 minutes per session. The patients are not provided with any follow-up or support from health professionals from the end of the intervention period until follow-up at 52-weeks. However, patients are allowed to contact the health professionals at the health promotion centre at any time if necessary.

Interval Walking Group with support (IWTsupport-group)

Patients in the Interval Walking Group with support (IWTsupport-group) are also encouraged to do IWT with the InterWalk app three times per week. All patients in the IWTsupport-group receive additional motivational support by the health professionals at the promotion centre (see below for information regarding the motivational support).

Motivational support (phase two)

The motivational support is summarised in Table 4. The motivational intervention consists of four motivational interviews with individual goal setting and weekly Short Message

Service via the mobile phone (a SMS-track), (see Figure 5 and 6). Furthermore, patients have the opportunity to participate in IWT at predefined timeslots with an Interval Walking Ambassador in the local community near the health promotion centre (see Figure 1).

Motivational interview and goal setting: All health professionals from the municipalities are well-educated in conducting the motivational interview with patients. All health professionals working in a health promotion centre in Denmark are obligated to participate in formalised motivational interviewing courses conducted by educators with psychological background. The Motivational interview is a semi-structured interview used to structure the communication between the patient and the health professional. The interview works as a partnership where focused and detailed questions reveal and visualize the patients motivation and barriers towards behaviour change and acknowledgement of patient autonomy.[26] Four motivational interviews are scheduled for each patient in the IWT support-group. See Table 4 for more detail. The motivational interview seek to help the patients reflect on their physically active habits and to set individual motivating goals related to everyday life.[27] The health professional secures all notes and reflections from the interview in the InterWalk database. As more than one interview is conducted over the trial period fidelity may be ensured when the health professional uses the patient's reflections from the former interview to help reflect upon motivation and barriers towards changes in the next motivational interview. The goal setting is based on the S.M.A.R.T.-principle derived from the Goal Setting Theory developed by Edwin Locke.[28] S stands for Specific

(e.g. what do I want to accomplish?), M for Measurable (e.g. specific and measurable), A for achievable (realistic), R for relevant (individual goals) and T for timely (not too big to achieve in a short period).[29]

Table 4. MOTIVATIONAL INTERVIEWS WITH INDIVIDUAL GOAL SETTING

PHASE TWO, IWTsupport-group

<i>Four semi-structured motivational interviews with individual goal setting,</i>	<ul style="list-style-type: none"> ○ The interviews aim at helping the patient to reflect on why and how physical activity can be incorporated in everyday life ○ Make informed choices regarding behavioral changes regarding physical activity ○ Relate to own everyday life ○ Clarify barriers and facilitators of importance for the individual ○ Two to three individual goals are set at all interviews ○ The goals is based on need in the individual everyday life
---	--

A short resume with the individual goal setting is written after all interviews in the database. The written text is prospectively incorporated in the following interviews with the patient at the health promotion centre

The interviews are placed in Week 16, 20, 28, 40 post baseline-test. Goal setting in the interviews are based on the *the S.M.A.R.T.- principle derived from the Goal Setting Theory developed by Edwin Locke*. [28]

Short Message Service (henceforth referred to as text message) enables inexpensive and possibly effective interaction between patients and health professionals at any time or place.[30,31] Communication as well as feedback is believed to enhance motivation through feelings of competence and relatedness [32], which may positively affect adherence to treatment. Text messages have shown positive effect on various health outcomes including diabetes self-management when used in behavior change interventions. Further, a higher effectiveness and lower attrition rate has been observed when customized and tailored messages is used.[30] In the present study, the patient receives two types of text messages during phase two (see Figure 4 and 5). The first type is a weekly and interactive

Effect of Interval walking on type 2 diabetics

BMJ Open

1
2
3
4
5
6
7
8
9 text message consisting of questions regarding the amount of IWT performed during the past
10 week (see Figure 4). The patients are required to give feedback by returning a text message
11 with one of the three response options provided. If the patient does not reply for two
12 consecutive weeks, or if the patient answers that she/he has not been walking, a personal
13 phone call to the patient is conducted from a health professional from the local health
14 promotion centre. The aim of the call is to encourage and help the patient to plan IWT to fit
15 the individual life of the patient. The second type of text message is sent every fourth week,
16 encouraging the patients to perform the walking test using the InterWalk app without a
17 requirement of feedback (see Figure 5).

35 *Interval Walking Ambassadors:* Using peers to educate other patients with
36 T2D has shown effective in providing ongoing support over a longer period.[33,34] In this
37 study, volunteer patients with T2D are recruited through the Danish Diabetes Association,
38 where a consultant contacts possible patients via e-mail. The Interval Walking Ambassadors
39 do IWT locally in phase two with patients from the IWTsupport group. The Interval
40 Walking Ambassadors receives a two-day training programme in the participating
41 municipality by researchers from the InterWalk research group. At any time during phase

33 *Control intervention – Standard care*

34
35 Patients in the control group receive the standard rehabilitation treatment offered to
36 patients with T2D in Denmark in a multimodal setting including physical activity (phase
37 one, Figure 1). The duration of rehabilitation treatment differs between participating
38 municipalities, but may not be shorter than eight weeks during phase one. At the end of the
39 standard care rehabilitation program in the municipalities there is no follow-up on the
40 exercise intervention, which is the normal procedure in Danish municipalities (phase two,

The participating municipalities offer group exercise twice a week at the health promotion centres with 6-15 patients participating depending on the population size in the participating municipality. The content of the group exercise period is based on clinical guidelines in Denmark. A typical session is structured with first a short warm-up session followed by a strength and cardio part and finished with a cool-down period with strengthening (See Table 2). Furthermore, it is recommended that the patients have regularly consultation at the general practitioner every third month.

Additional rehabilitation care (Co-interventions)

All patients receiving rehabilitation at either a health promotion centre or at the hospital receives an offer of specific disease related patient education, diet counselling and smoking cessation.[35] It is optional whether the patient participate in one or all additional offers.

Disease specific patient education includes a section focused on behaviour modification and self-management and a specific part on diseases were the patients get knowledge regarding sequelae. *Diet counselling* regarding nutritional advice when living with T2D is handled by a dietitian. *Smoking cessation* is either group based or in individual process and is handled by smoking cessation counsellors.

Previous studies have established that physical activity influences glycaemic control [36] and Karstoft and colleagues (2013) has shown that physical activity with Interval Walking Training had effect on glycaemic control in patients with T2D. [15] Moreover, medication and dietary interventions have also proven to improve glycaemic control and reduce disease related complications.[37–39] In the present trial the primary outcome focus on physical activity in relation to everyday life.

Data on the primary and secondary outcomes are obtained at baseline, post intervention (after 8-12 weeks) and 52 weeks after enrolment (Table 5). To standardize all measurements between health professionals and participating centres, all health professionals uses standardised protocols crafted for the trial regarding procedures and measurements. All data are entered directly in an online database (see section: Data management and quality control).

Effect of Interval walking on type 2 diabetics

* Article 1: The effectiveness of smartphone delivered Interval Walking Training on moderate-and-vigorous physical activity versus standard care in patients with type 2 diabetes: a parallel group single-blinded randomized controlled trial.

†Article 2: Baseline characteristics and personality traits in patients with type 2 diabetes: descriptive study of all participants

‡Article 3: Nay Sayers – Characteristics of patients who does not want to be part of a physical activity study related to everyday life; all patients referred to the health promotion centre in the municipalities participating in the randomized controlled trial.

§Article 4: Effectiveness of smartphone delivered Interval Walking Training versus standard care in patients with type 2 diabetes on HbA1c and HDL, high-density lipoprotein; LDL, low-density lipoprotein: A sub-study to the randomized controlled trial (The InterWalk Trial, article 1), measured in a sub-sample (n=40).

Primary outcome

The primary outcome is change in moderate-to-vigorous-intensity physical activity from baseline to 52-week follow-up.

Secondary outcomes

The key secondary outcome changes in motivation for sustaining a behavioural change with physical activity in everyday life at 52-week follow-up.

Other secondary outcomes of interest are changes in patients' fitness level measured as VO₂-peak by the standardised walking test (part of the InterWalk application) and health-related quality of life. Strength in the lower extremities, adherence to intervention and impact of personality traits on physical activity in everyday life are also considered exploratory secondary outcomes. All outcomes are measured at baseline, after intervention and at 52-week follow-up (see Figure 2).

Data collection

Level of daily moderate-to-vigorous-intensity physical activity

It is important to gain knowledge into physical activity in everyday life. To determine level of daily moderate-to-vigorous-intensity physical activity a hip-mounted physical activity monitor (Axivity AX3, Newcastle, UK) is worn for seven consecutive days, at three time periods during the trial period; after baseline-test, after the intervention period and again at

1
2
3
4
5
6
7
8
9 52-weeks follow-up. The monitor is fixed using adhesive tape (Leukomed T, BSN medical,
10 Germany) on right side the lumbar spine. Additionally, a monitor is fixed on on the lateral
11 side of the right thigh (Leukomed T, BSN medical, Germany) for supporting information
12 about posture.[25] The patients are instructed not to remove the physical activity monitor at
13 any time during the three time periods. If de-attached, the participants are trained in fixing
14 the monitors correctly and are instructed to note the incident. If the patients need help in
15 fixing the monitors correctly the health professionals at the health promotion centre are
16 educated to help.

28 *Physical activity diary*

29
30 In order to validate the physical activity level during the seven days with physical activity
31 monitors we ask the patient to complete a seven-day diary to report number of work- and
32 sleep hours, bicycling and strength training sessions at the three time periods on a daily
33 basis. The physical activity monitor and the diary are returned free-of-charge via mail. The
34 patient is contacted by phone after within one week if the physical activity monitors are not
35 returned as expected.

4
5
6
7
8
9 (BREQ-2) which measures individual motivation for physical activity. The questionnaire
10 consists of 19 questions in a 0-4 Likert format.[40] In addition to the questionnaire, patients
11 are asked to answer four questions in a 0-4 Likert format, regarding motivation for physical
12 activity after being diagnosed with T2D.
13
14
15
16

17 18 19 20 *Health Related Quality of Life*

21 The patients Health Related Quality of Life is very important to maintain after being
22 diagnosed with T2D.[41] To gain knowledge into the individual perception of quality of life
23 on a physical and mental level we use the Short-Form Health Survey (SF-12). The
24 questionnaire consists of 12 questions and uses a Likert scale of 1-3 for the physical function
25 items; 1-5 for the bodily pain, social function, and general health perceptions items; 1-6 for
26 the vitality and mental health; and a dichotomous scale of yes/no for the presence of role
27 function limitations. The higher score, the higher level of health or functioning.[42]

33
34
35
36
37
38
39

40 *Maintenance of behaviour change with physical activity*

41 Automaticity of behaviour is essential when new habits become present in the everyday
42 life.[43] To measure if the patient has adopted new habits as a result of the intervention we
43 ask the patient to answer four questions from The Self-Report Habit Index. The Index uses a
44 0-4 Likert format and the four questions to be answered measures automatic activation,
45 frequency of behaviour and relevance to self-identity related to physical activity.[44]

56
57
58
59
60

VO₂-peak

VO₂-peak is measured by a validated and standardised walking test consisting of 5 stages incorporated in the InterWalk app; 1) 30 sec. of standing still, 2) 2 min. of slow walking 3) 2 min. of walking at moderate intensity 4) 2 min. walking at high intensity 5) 1 min. walking at highest intensity possible. The four paces are self-selected (See, Figure 3 and 4).[25] The test is performed with an iPod placed in the pocket at the hip and the instructions are delivered from the app through earphones. To ensure the right walking intensity in the intervention period, the patients are asked to perform the test every 4th week.[16]

Strength in the lower extremities

The sit-to-stand test (30 seconds) measures the lower body strength and will be administered using a chair without arms. The patient is encouraged to complete as many full stands as possible within a 30-sec time limit.[45]

Adherence to the intervention

Adherence is determined by an evaluation and quantification of the electronic log of data from the InterWalk app to the central database of all uploaded data.

The “Recent Physical Activity Questionnaire” (RPAQ) has 9 main questions, which covers 4 domains of physical activity: domestic life, work, recreation and transport. Physical Activity is estimated in MET’s (Metabolic Equivalent). In answering the questions in the questionnaire, the patient will answer in regards to the last four weeks with physical activity in the everyday life.[46]

Personality traits

The NEO-Five Factor Inventory (NEO-FFI) [47] consists of 60 questions in a 0-4 Likert format constructed by selecting 2 items from each of the six facets characterizing each of the five personality traits (Neuroticism, Extraversion, Openness, Agreeableness, Conscientiousness) assessed by NEO-PI-R. The Sensation Seeking Scale (SES) [48] is a 40 items self-administered questionnaire consisting of 40 questions designed to test the tendency towards varied, novel and intense sensations.

Demographic, social economic and anthropometry measures

Information on height, weight, waist and hip circumference is collected before inclusion through an electronic questionnaire at the first formal meeting at the health promotion centre and after the intervention period and again at 52-week follow-up. Waist circumference is measured at the point between the top of the iliac crest and the bottom of the costae regardless of the placement of the umbilicus. A Tanita stadiometer is used to measure height

1
2
3
4
5
6
7
8
9 and an electronic weight to measure weight. Data on self-reported information together with
10 relevant national registers will be used to obtain information regarding hospitalization, co-
11 morbidities, medical history, use of medicine and mortality.
12

13
14
15 *Height* measurement is conducted using a portable altimeter (Tanita
16 Stadiometer). The measurement is done without shoes and is repeated two times with each
17 measure to nearest 0,1 cm. If the two measures are dissimilar with more than 0,5 cm, then
18 the measurement is repeated. *Weigh* is measured in kilograms (kg) using an electronic
19 weight. The measure is repeated two times with each measure to nearest 0,1 cm. If the two
20 measures are dissimilar with more than 0,5 kg, then the measurement is repeated a third
21 time. The patient is weighed fully dressed and one kilo is subtracted from each measure.
22
23 *Hip circumference* is measured on the skin on the crest of the hipbone. The patient is asked
24 to place a finger in the belly bottom and the measure is done with a tape measure (2
25 meters) placed on the upper side of the patients' finger. If the two measures are dissimilar
26 with more than 0,5 cm, then the measurement is repeated a third time.

9 promotion centres, during the trial period. In case of severe adverse events, the Scientific
10 Ethical Committee of the Capital Region of Denmark is informed.
11
12

13 14 15 **Sample size considerations** 16

17 The minimum difference of interest (MDI) is 10 minutes per day. Based on existing
18 experimental evidence, we expect the standard deviation (SD) of the change in moderate-
19 and-vigorous physical activity from baseline to 12 month follow up to be between 1.2 – 2.3
20 times the effect size.[49,50] Therefore, SD twice the MDI (20 min of moderate-and-
21 vigorous physical activity) per day was applied in the sample size calculations. After
22 applying Bonferroni adjustment due to multiple comparisons in the three group trial a total
23 of 190 participants are needed to obtain a statistical power (1- β) of 80% with an α of 0.017
24 (two-tailed). Allowing for an attrition rate of 30%, 272 patients (91 in the control group
25 and 181 in experimental group) are recruited. The setting enables recruitment until
26 December 15st 2016. The sample size is truncated at 272 participants or the N reached at
27 the end of recruitment period - whatever is reached first (see section 'Participants').

9 the post intervention test (phase two). A health professional associated with the trial,
10 telephones the patient and inform about random allocation after returning the PA monitors to
11 either IWT-group or IWTsupport-group. The patients are stratified by gender to ensure an
12 equal number across all groups. The allocation sequence is generated through a standardised
13 computer program by an independent researcher (RC). The allocation sequence is concealed
14 until the trial arms are assigned. A Flow of patients is depicted in Figure 2.
15
16
17
18
19
20
21
22

23 **Blinding**

24
25 The scientific staff is blinded to patient allocation from baseline to the 52-week follow-up is
26 completed for all patients. The health professionals at the promotion centre are not blinded
27 to allocation to either standard care or experimental groups.
28
29
30
31
32
33

34 **Statistical methods**

35
36 All analyses will be conducted according to the Intention-To-Treat principle. Continuous
37 endpoints will be analysed using repeated measures analysis of covariance in a mixed
38 linear model. Categorical and dichotomous end points will be analysed with the use of
39 logistic regression. The model will include with group, and sex as fixed effects, with the
40 baseline value as a covariate.
41
42
43
44
45
46
47

48 All patients randomised to one treatment, will be analysed according to the treatment to
49 which the patient was allocated, irrespective of whether they received this or some other
50 treatment, or no treatment at all. The ITT population will be handled all patients randomised

60

to the three treatment arms, and the dataset is equal to the “all patients randomized set” (APRS). Missing values due to patients’ absence from follow-ups or withdrawal from the study are to be expected in clinical trials. Several approaches are described for handling missing data in the ITT analysis, and among them “baseline observation carried forward” (BOCF: i.e., a null-responder imputation, where the level at baseline is also considered the last). A linear mixed model analysis includes all patients with a baseline assessment, and includes both fixed and random factors. Thus, repeated linear mixed model method is chosen for the primary analyses in this trial (i.e., no data imputation), whereas the BOCF imputation, as well as the ‘Per Protocol’ population will be applied for the purpose of sensitivity analysis. Also, we will explore whether potentially important covariates such as age, sex, disease duration, degree of overweight (using BMI), and smoking status at enrollment/baseline could potentially confound the results from the primary analyses (i.e. an extra pre-specified sensitivity analysis). Exploratory analyses of the treatment effects will be performed on some the secondary outcomes.

Data management and quality control

All data are entered in an SSL-secured, online-based database developed by the Danish Stakeholder Help2Run (CVR: 34801088). The online-based database logistically handles the data gathered at baseline, after intervention in phase one, and during follow-up (phase two) and after 52 weeks. Data on demography, measurements, tests and questionnaires are

1
2
3
4
5
6
7
8
9 entered directly in the database available via a project-specific
10 homepage ([http://www.runsafe.dk/mtd/login/admin-](http://www.runsafe.dk/mtd/login/admin-signi)
11 [signihttps://www.runsafe.dk/mtd/login/admin-signin](https://www.runsafe.dk/mtd/login/admin-signin)). A protected back-end system
12 (https://www.runsafe.dk/mtd/admin) is used to logistically handle information on
13 demography, measurements, tests and questionnaires on each participant in the trial (for
14 information on Interval Walking Training using the InterWalk app see '*Interval Walking*
15 *Training using The InterWalk Application*'). The system was approved in 2014 after an
16 inspection by the Danish Data Protection Agency. Access to personalized data from
17 the InterWalk participants is only possible using a personalized username and password.
18 Only specified researchers are allowed to administrate the back-end system and each
19 researcher and project member with access to the back-end has a unique username and
20 personal password for the back-end system. All activities, including changing data and
21 downloading data, in the back-end system are logged in accordance with the rules and
22 regulations from the Danish Data Protection Agency. A unique subject ID number will be
23 subscribed to all patients in order to anonymize data. The identification key (ID to personal
24 information) will be encrypted and stored securely and separately from the unique ID
25 number on a secure database.

48 ***Ethics and Dissemination***

49
50 The InterWalk trial contributes with important knowledge on different treatment approaches
51 in the rehabilitation of patients with T2D. Physical activity and exercise have beneficial
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 effect on patients with T2D when the interventions are conducted in well-designed efficacy
10 studies.[2,4,6] However, little is known on whether this effect also is present in effectiveness
11 studies or “real-world setting” studies. These studies are of great importance and relevance
12 regarding evidence-based medicine highlighting the importance of the InterWalk trial.
13
14

15
16
17 The InterWalk trial has a pragmatic design that allows for different
18 intervention periods in the participating municipalities. Furthermore, the interventions are
19 conducted directly in the clinical setting giving a more reliable frame of the experienced
20 challenges in a population with T2D. We believe that the implementation of the study results
21 will have a smoother implementation phase, as the health professionals already are familiar
22 with the preceding's.
23
24
25
26
27
28
29

30
31 The trial gives valuable insight into the impact of different motivational and
32 supportive tools as well as knowledge about individual motivation and the impact on
33 sustaining a newly acquired behaviour change regarding physical activity in everyday life.
34
35
36

37 Interval Walking Training is expected to be a suitable and effective way of
38 providing moderate-vigorous physical activity for at large group of patients with T2D. IWT
39 can be done at any time and anywhere and is thus integrated and tailored to fit individual
40 everyday life. The overall objective is to promote lifelong physical activity for the individual
41 and we believe that experiences from the present trial can help when planning future
42 interventions with IWT to patients with various lifestyle diseases e.g. coronary heart
43 diseases.

It is a major advantage that the trial is designed as a randomised controlled trial in a “real-world setting” with a study population representing patients with T2D referred to rehabilitation. Furthermore, data and results are collected consecutively and directly in the clinical setting in which the interventions are to be used after the trial. Together with the very limited number of inclusion and exclusion criteria and a stratification of patients on gender secures external validity of the trial and thus will add important information to the current body of evidence on T2D treatment.

All data from eHealth solutions as the InterWalk app are electronically monitored. The patient is not dependent on opening hours at the health promotion centre as the InterWalk is either installed on an iPhone or an iPod. This gives a unique possibility for the patient to be physically active whenever it fits in their everyday life.

We acknowledge that physical activity only has effect when adherence is high, which is why we first compare standard care with interval walking for a shorter period (phase one) followed by a re-allocation of patients in the experimental group to either interval walking with or without motivational support (phase two). All groups have a 52-week follow-up. The trial design enables us to investigate if patients are able to maintain a newly acquired behaviour change with physical activity in everyday life with or without motivational support for a longer period.

All personalized data and measures are stored on a central online-based database developed to logistically handle all data collected at baseline and during follow-

1
2
3
4
5
6
7
8
9 up. The backend system (<https://www.runsafe.dk/mtd/admin/>) secures all information
10 from each patient. The construction of the database with personalized usernames,
11 passwords, and specific permissions to all health professionals and administering
12 permissions to scientific staff in the backend secures all data. Furthermore, all activities are
13 logged.
14
15
16
17
18

19 All outcomes measures are assessed blinded to allocation at baseline and the
20 primary outcome is assessed blinded to intervention in the experimental group after the
21 intervention period. All measures are conducted by the health professionals at the health
22 promotion centres and are blinded for allocation after intervention in the experimental group
23 with IWT until after return of the physical activity monitors by the patient. All statistical
24 analyses are blinded to researchers, reducing the risk of detection and interpretation
25 bias.[51–53] All secondary outcomes, but VO₂-peak and the Sit to Stand Test are self-
26 reported and by nature likely to be biased. The patients answer questionnaires independently
27 of the health professionals at the health promotion centres.
28
29
30
31
32
33
34
35
36
37
38

39 The secondary outcomes of motivation for physical activity and behaviour
40 change are of highly importance as knowledge concerning motivational support and
41 maintenance of effect (new habits with physical activity) to our knowledge is lacking in
42 patients with T2D. This knowledge will help health professionals to better tailor the
43 treatment and hereby potentially achieve a higher adherence to the programme following the
44 supervised intervention.

9 The limitations in this trial are similar to those of other exercise trials where
10 physical testing and time-of-day and day-to-day variation constitute a challenge. We have
11 standardised all testing protocols for all procedures to reduce the variation and run a
12 routine program of on-going calibration and training of the health professionals.
13
14
15
16

17 The trial is conducted in accordance with the Helsinki Declaration II.[54] All
18 eligible patients receive written and oral informed consent prior to inclusion before any
19 additional trial procedures. Data on all screened patients are registered in order to report
20 characteristics of in-eligible patients and written informed consent is also obtained from
21 these patients. The patients can withdraw from the trial at all times during the trial period.
22 This has no consequence for any other future treatment. If patients discontinue the trial
23 intervention, standard care is offered for the rest of the intervention period. All results from
24 the trial, negative, positive or inconclusive results, are disseminated in international peer-
25 reviewed scientific papers and at national and international conferences. We follow the
26 guidelines from the International Committee of Medical Journal Editors when authorship is
27 determined. The results will be reported when all long-term data become accessible.

9 The inclusion period started in January 2015 and is scheduled to finish in December 2017
10 with a 52-week follow-up. To ensure enrolment of patients in the trial we are open for
11 collaborations with new municipalities during the trial period. So far the trial has resulted
12 in collaboration with both rural and urban municipalities in Denmark. The inclusion rate is
13 carefully monitored every week by the research team. In November 2016, 216 patients had
14 been enrolled in the trial.

SPIRIT 2013 Checklist: Recommended items to address in a clinical trial protocol and related documents*

Section/Item	ItemNo	Description	Page
Administrative information			
Title	1	Descriptive title identifying the study design, population, interventions, and, if applicable, trial acronym	1
Trial registration	2a	Trial identifier and registry name. If not yet registered, name of intended registry	2 & 5
	2b	All items from the World Health Organization Trial Registration Data Set	4, 31, 1, 5, 7-22, 6, 26, 23
Protocol version	3	Date and version identifier	N/A
Funding	4	Sources and types of financial, material, and other support	33
Roles and responsibilities	5a	Names, affiliations, and roles of protocol contributors	33
	5b	Name and contact information for the trial sponsor	N/A
	5c	Role of study sponsor and funders, if any, in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication, including whether they will have ultimate authority over any of these activities	N/A
	5d	Composition, roles, and responsibilities of the coordinating centre, steering committee, endpoint adjudication committee, data management team, and other individuals or groups overseeing the trial, if applicable (see Item 21a for data monitoring committee)	7, 16, 17, 31
Introduction			
Background and rationale	6a	Description of research question and justification for undertaking the trial, including summary of relevant studies (published and unpublished) examining benefits and harms for each intervention	3, 7-22
	6b	Explanation for choice of comparators	4, 16, 29
Objectives	7	Specific objectives or hypotheses	4
Trial design	8	Description of trial design including type of trial (eg, parallel group, crossover, factorial, single group), allocation ratio, and framework (eg, superiority, equivalence, noninferiority, exploratory)	4
Methods: Participants, interventions, and outcomes			
Study setting	9	Description of study settings (eg, community clinic, academic hospital) and list of countries where data will be collected. Reference to where list of study sites can be obtained	4
Eligibility criteria	10	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will perform the interventions (eg, surgeons, psychotherapists)	5, 6

1				
2	Interventions	11a	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	5-22
3				
4				
5		11b	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving/worsening disease)	14, 21
6				
7				
8				
9		11c	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return, laboratory tests)	12, 14
10				
11				
12		11d	Relevant concomitant care and interventions that are permitted or prohibited during the trial	14
13				
14	Outcomes	12	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	23
15				
16				
17				
18				
19				
20				
21	Participant timeline	13	Time schedule of enrolment, interventions (including any run-ins and washouts), assessments, and visits for participants. A schematic diagram is highly recommended (see Figure)	5, 24, 27
22				
23				
24				
25	Sample size	14	Estimated number of participants needed to achieve study objectives and how it was determined, including clinical and statistical assumptions supporting any sample size calculations	25
26				
27				
28				
29	Recruitment	15	Strategies for achieving adequate participant enrolment to reach target sample size	4
30				

Methods: Assignment of interventions (for controlled trials)

Allocation:

31				
32				
33				
34				
35	Sequence generation	16a	Method of generating the allocation sequence (eg, computer-generated random numbers), and list of any factors for stratification. To reduce predictability of a random sequence, details of any planned restriction (eg, blocking) should be provided in a separate document that is unavailable to those who enrol participants or assign interventions	27
36				
37				
38				
39				
40				
41	Allocation concealment mechanism	16b	Mechanism of implementing the allocation sequence (eg, central telephone; sequentially numbered, opaque, sealed envelopes), describing any steps to conceal the sequence until interventions are assigned	27
42				
43				
44				
45	Implementation	16c	Who will generate the allocation sequence, who will enrol participants, and who will assign participants to interventions	27
46				
47				
48	Blinding (masking)	17a	Who will be blinded after assignment to interventions (eg, trial participants, care providers, outcome assessors, data analysts), and how	28
49				
50				
51		17b	If blinded, circumstances under which unblinding is permissible, and procedure for revealing a participant's allocated intervention during the trial	21
52				
53				

Methods: Data collection, management, and analysis

1				
2	Data collection methods	18a	Plans for assessment and collection of outcome, baseline, and other trial data, including any related processes to promote data quality (eg, duplicate measurements, training of assessors) and a description of study instruments (eg, questionnaires, laboratory tests) along with their reliability and validity, if known. Reference to where data collection forms can be found, if not in the protocol	24
3				
4				
5				
6				
7				
8		18b	Plans to promote participant retention and complete follow-up, including list of any outcome data to be collected for participants who discontinue or deviate from intervention protocols	22
9				
10	Data management	19	Plans for data entry, coding, security, and storage, including any related processes to promote data quality (eg, double data entry; range checks for data values). Reference to where details of data management procedures can be found, if not in the protocol	31
11				
12				
13	Statistical methods	20a	Statistical methods for analysing primary and secondary outcomes. Reference to where other details of the statistical analysis plan can be found, if not in the protocol	28
14				
15				
16		20b	Methods for any additional analyses (eg, subgroup and adjusted analyses)	N/A
17				
18		20c	Definition of analysis population relating to protocol non-adherence (eg, as randomised analysis), and any statistical methods to handle missing data (eg, multiple imputation)	N/A
19				
20				
21				
22				
23				
24	Methods: Monitoring			
25				
26	Data monitoring	21a	Composition of data monitoring committee (DMC); summary of its role and reporting structure; statement of whether it is independent from the sponsor and competing interests; and reference to where further details about its charter can be found, if not in the protocol. Alternatively, an explanation of why a DMC is not needed	31
27				
28				
29				
30				
31		21b	Description of any interim analyses and stopping guidelines, including who will have access to these interim results and make the final decision to terminate the trial	N/A
32				
33				
34	Harms	22	Plans for collecting, assessing, reporting, and managing solicited and spontaneously reported adverse events and other unintended effects of trial interventions or trial conduct	21, 31
35				
36				
37	Auditing	23	Frequency and procedures for auditing trial conduct, if any, and whether the process will be independent from investigators and the sponsor	N/A
38				
39				
40				
41	Ethics and dissemination			
42				
43	Research ethics approval	24	Plans for seeking research ethics committee/institutional review board (REC/IRB) approval	5
44				
45	Protocol amendments	25	Plans for communicating important protocol modifications (eg, changes to eligibility criteria, outcomes, analyses) to relevant parties (eg, investigators, REC/IRBs, trial participants, trial registries, journals, regulators)	5
46				
47				
48				
49	Consent or assent	26a	Who will obtain informed consent or assent from potential trial participants or authorised surrogates, and how (see Item 32)	5
50				
51				
52		26b	Additional consent provisions for collection and use of participant data and biological specimens in ancillary studies, if applicable	32
53				
54				
55	Confidentiality	27	How personal information about potential and enrolled participants will be collected, shared, and maintained in order to protect confidentiality before, during, and after the trial	31
56				
57				
58				
59				
60				

1				
2	Declaration of interests	28	Financial and other competing interests for principal investigators for the overall trial and each study site	33
3				
4	Access to data	29	Statement of who will have access to the final trial dataset, and disclosure of contractual agreements that limit such access for investigators	31
5				
6				
7	Ancillary and post-trial care	30	Provisions, if any, for ancillary and post-trial care, and for compensation to those who suffer harm from trial participation	N/A
8				
9				
10				
11	Dissemination policy	31a	Plans for investigators and sponsor to communicate trial results to participants, healthcare professionals, the public, and other relevant groups (eg, via publication, reporting in results databases, or other data sharing arrangements), including any publication restrictions	31
12				
13				
14				
15				
16		31b	Authorship eligibility guidelines and any intended use of professional writers	31
17				
18		31c	Plans, if any, for granting public access to the full protocol, participant-level dataset, and statistical code	N/A
19				
20	Appendices			
21				
22	Informed consent materials	32	Model consent form and other related documentation given to participants and authorised surrogates	N/A
23				
24				
25	Biological specimens	33	Plans for collection, laboratory evaluation, and storage of biological specimens for genetic or molecular analysis in the current trial and for future use in ancillary studies, if applicable	32
26				
27				

*It is strongly recommended that this checklist be read in conjunction with the SPIRIT 2013 Explanation & Elaboration for important clarification on the items. Amendments to the protocol should be tracked and dated. ABSTRACT:**Introduction**

Physical activity is a cornerstone in Type 2 diabetes (T2D) rehabilitation. Effective long-term and low-cost strategies to keep these patients' physically active are needed. However, maintaining physical activity behaviour is difficult once formalised interventions end. Structured exercise training supported by mobile technology and remote feedback is potentially an effective strategy.

The objective of the trial is to investigate whether mobile health support using the InterWalk application for smartphones is effective in increasing physical activity levels in persons with T2D over time compared to standard care.

We investigate whether Interval Walking Training (IWT) using the InterWalk application is superior to Danish municipality-based rehabilitation in increasing moderate-and-vigorous physical activity levels in patients with T2D across 52 weeks. Secondary, we hypothesize that a motivational programme added from end of intervention to 52-weeks further increases level of physical activity in everyday life in patients with T2D.

Methods and analysis

The trial is a parallel-group, open-labelled, randomised controlled trial with long-term follow-up at 52-week including patients with T2D. The primary outcome is change in moderate-and-vigorous physical activity. The key secondary outcome includes motivation for physical activity behaviour change. Other secondary outcomes are VO_2 -peak, strength in

1
2
3
4
5
6
7
8
9 the lower extremities. Exclusion criterion is medical contraindication to exercise. We
10 include up to 246 patients and randomly allocate them into a control (standard group) or an
11 experimental group (8-12 weeks of IWT supported by the smartphone-based InterWalk
12 application) in a 1:2 fashion. After intervention, the experimental group is randomly
13 allocated into two follow-up conditions with unsupervised IWT with or without motivational
14 support until 52-week follow-up. The Intention-To-Treat principle is applied.

40 **STRENGTHS:**

- 41 ○ The trial is the largest of its kind, and meets the criteria for high quality randomized
42 controlled trials with central randomization and use of valid and reliable measures.
43
- 44 ○ The trial has a long-term follow-up period of 52-weeks from baseline.

Effect of Interval walking on type 2 diabetics

BMJ Open

- The trial has high external validity with relevance for the clinical setting as it is performed within clinical practice and includes a limited use of inclusion/exclusion criteria's.

LIMITS:

- The trial has several collaborators in the setup which may cause variation in the testing procedures.
- Lack of clinical endpoints e.g. depression and mental health
- The length of the intervention periods varies between the three collaborating municipalities may influence the results of the trial.
- There may be a risk of contamination in the control group as the InterWalk application can be downloaded in App Store.

INTRODUCTION

Physical activity (PA) is a cornerstone in the clinical care of patients with type 2 diabetes (T2D).[1] PA activity has beneficial effect on glycaemic control and other key metabolic risk factors [2,3], as well as improvements in quality of life.[4,5] Furthermore, supervised long-term PA interventions have proven effective in improving glycaemic control.[2,6] However, experimental evidence does not support the efficiency of advice about physical activity alone.[7] As the number of patients with T2D is estimated to rise to 500 million by 2030 worldwide [8,9] the implementation of structured, long-term and supervised exercise regimes constitutes a large societal challenge and is not feasible. Thus, novel strategies to increase physical activity among patients with T2D are needed.

Smartphones have been used as a tool to register exercise, diet, weight and plasma glucose levels, but the evidence for using a smartphone as an exercise device and a self-management tool in the diabetes care is lacking.[10] However, emerging evidence suggest that eHealth solutions using information and communication technologies [11] can educate and engage patients with T2D in long-term self-management.[12–14] Due to the large ingress and ownership of smartphones, a smartphone-supported approach could prove feasible in increasing physical activity among patients with T2D and accommodate the increasing prevalence of T2D.

Efficiency of Interval Walking Training (IWT) in patients with T2D has been established.[15] In the study by Karstoft and co-workers, IWT was administered and

1
2
3
4
5
6
7
8
9 monitored using a small exercise computer (JD-mate). IWT induced significant improvements
10 in physical fitness level, body composition and glycaemic control and in adherence of more
11 than 85% over a 16 weeks period.[15] The potential benefits of implementing eHealth
12 solutions in T2D management and the apparent health benefits of and adherence to IWT gave
13 rise to the development of the InterWalk application (InterWalk app) to deliver IWT.[16]
14
15
16
17
18

19
20 There is a lack of knowledge about the integration of PA in the everyday life
21 of the patient following rehabilitation interventions.[17] It is, however, known that
22 successful behavioural change depends on an on-going maintenance of individual
23 motivation regarding the behaviour and behavioural change itself.[18] Furthermore, time
24 since onset of diagnosis, unhealthy behaviour and own beliefs about the cause of the
25 problem, together with the number of previous attempts to change and support from
26 partners, peers and health professionals are of relevance.[18] This underlines the need for
27 new interventions with a direct focus on motivational support and self-control regarding
28 sustaining a newly acquired behavioural change with PA. To better target and structure
29 manageable interventions related to patients with T2D, understanding patients' individual
30 priorities and values are crucial. In this regard, knowledge of individual motivation and self-
31 efficacy to initiate behavioural changes becomes essential to understand.[18]

8 follow CONSORT guidelines (CONSolidated Standards Of Reporting Trials) for non-
9 pharmacological interventions.[20]
10
11

12 13 14 15 **Trial objective and hypothesis**

16
17 The objective of the trial is to investigate whether mobile support using the InterWalk
18 application for smartphones is effective in increasing physical activity levels in persons with
19 type 2 diabetes over time compared with a standard care rehabilitation program.
20
21

22 We investigate the effectiveness of the implementation of Interval Walking Training using the
23 InterWalk application in the Danish municipality-based rehabilitation program and study
24 whether the Interval Walking Training is superior to standard care in increasing moderate-
25 vigorous physical activity 52 after weeks. Furthermore, we expect that a motivational support
26 program added from end of the intervention to 52-weeks, will increase the physical activity
27 level in patients with type 2 diabetes and help maintaining a physically active everyday life
28 long-term.

42 **METHODS AND ANALYSIS**

43 44 *Trial design and setting*

45
46 The trial is a 52-week parallel-arm, open-labelled, randomised controlled trial. The
47 participants are randomly allocated into two groups, 1) standard care or 2) experimental
48 group with moderate-and-vigorous physical activity level, doing interval walking

facilitated by the InterWalk app. After an 8-12-week intervention period, patients in the experimental group are allocated to do interval walking using the InterWalk app with or without motivational support provided by the health professionals (see Figure 1).

[INSERT FIGURE 1 ABOUT HERE]

The intervention is conducted at the health promotion centres in Danish municipalities and hospitals that consecutively are included as cooperation partners. The municipality of Copenhagen is the first collaborator in the trial. Patients are referred to rehabilitation by their general practitioner (GP). Trained health professionals (physical therapists, nurses and staff with a master's degree) working at the health promotion centres recruit the patients, deliver the interventions and conduct all testing. The overall organization of health care in Denmark is fully tax-financed with universal access to health care services. The Danish model is described in detail elsewhere [21,22] and chronic disease care (including T2D) management is in Denmark based in the Chronic Care Model.[23]

Briefly, GPs refer patients diagnosed with T2D to rehabilitation at either an out-patient clinic, within a municipality or at the hospital level in Denmark. The setting depends on stage of the disease, presence of complications and co-morbidities e.g. severe heart conditions, depression or mental illness. The municipality based rehabilitation primarily includes non-complicated patients (~80% of all patients).[21] If complications or

1
2
3
4
5
6
7
8
9 co-morbidities are present, patients are referred to treatment at a specialized clinic at a
10 hospital. Patients with a non-complicated course of disease receive rehabilitation
11 consisting of: 1) disease-specific patient education, 2) diet counseling, 3) smoking
12 cessation and 4) exercise. The composition of the individual rehabilitation program
13 depends however on disease progression and on the rehabilitation offered in the
14 municipality-based program or at the hospital. The general focus is patient empowerment,
15 disease-related self-care and prevention of a decay of the functional capacity of patients
16 with T2D.

All non-complicated patients diagnosed with T2D (out-patients), referred to a health promotion centre or hospital in the participating municipalities by their GP, are eligible if more than 18 years of age. A flow chart of participants is presented in Figure 2.

[INSERT FIGURE 2 ABOUT HERE]

The exclusion criteria are medical contraindications to exercise e.g. chronic complications in the locomotive apparatus, painful osteoarthritis or heart conditions.[24] Information is collected through medical records and at a screening interview with a health professional at the health promotion centre. Furthermore, patients are excluded if they do not want to be physically active in the rehabilitation setting or are already participating in other intervention studies at a health promotion centre. The patients have to be able to talk, read and understand the Danish language (for overview over in- and exclusion criterion, see Table 1).

Table 1. ELIGIBILITY CRITERIA

Inclusion criteria

- Diagnosed with type 2 diabetes
- Referred by General practitioner to a health promoting centre in participating municipality or hospital

Exclusion criteria

- < 18 years of age
 - Medical contraindications to exercise
 - Already participating in other exercise trials
 - Does not talk and read Danish
-

20 **Interventions**

21
22 The trial is developed in collaboration with the health professionals from the municipality
23 of Copenhagen in Denmark. The interventions are designed to reflect the clinical
24 rehabilitation settings in Denmark in order to increase the likelihood of implementation of
25 the programme following this trial, if proven superior. Health professionals from the
26 municipalities already providing the rehabilitation delivers all interventions in both the
27 control and experimental groups during the trial period. The investigators (LSV, CB and
28 HL) led four workshops (16 hours in total) with the health professionals during year 2014,
29 in which the interventions of the study and work routines were discussed in detail.
30 Furthermore, all participating health professionals underwent a thorough education
31 program (15 hours in total) involving all procedures and manuals in the trial. This was
32 done to ensure standardization of all procedures throughout the trial. In addition,
33 workshops were held from the start of the trial (January 2014) and hereafter every second
34 month. This is done to secure that the health professionals follow all procedures and
35 prepared manuals throughout the trial. The applicability of the trial results is hereby

8
9 increased, as the interventions are already part of the rehabilitation programme offered to
10 patients with T2D in the municipalities.
11

12
13 The interventions in the trial consist of two phases (Figure 1). In phase one (8-
14 12 weeks), patients are randomised to either a standard care group (control intervention) or
15 an experimental group doing IWT using the InterWalk app. The present trial uses the
16 standard care programme as control intervention and is conducted directly in the clinical
17 setting. All patients receive supervision across phase one. In phase two (40-44 weeks),
18 patients in the standard care group have no follow-up until 52 weeks post baseline. Patients
19 in the experimental intervention group are in phase two randomly allocated to either IWT
20 with or without motivational support (see section Experimental intervention – Interval
21 Walking with the InterWalk application). Additional rehabilitation care (co-interventions)
22 with disease-specific patient education, diet counseling and smoking cessation is offered to
23 all patients across the intervention groups. The interventions are summarized in Table 2.

Experimental intervention – Interval Walking Training with the InterWalk application

Patients allocated to the experimental intervention do interval walking after baseline test provided by health professionals (phase one). IWT is provided by health professionals to smaller groups of 3-12 patients. After the intervention period in phase two patients are allocated to either receive IWT without motivational support during follow-up (IWTgroup) or IWT with motivational support during follow-up (IWTsupport-group) (Figure 1). Trained health professionals conduct the IWT sessions (see below) and the motivational support in phase two. Table 2 gives an example of a typical week with interval walking in the experimental intervention group.

Interval Walking Training using The InterWalk Application

Interval Walking Training is performed using the InterWalk app, which works as a personal trainer as well as a monitoring unit allowing researchers to continuously and automatically monitor and store the physical activity level in a central database (Figure 3).[16]

Interval Walking Training is personalized through a standardised eight-minute walking test, performed with the app before engaging in IWT.[25] The InterWalk app guides the user in IWT with repeated cycles of 3 minutes fast and 3 minutes slow walking. During Interval Walking Training (IWT) the InterWalk app provides the patient with continuous feedback on the walking speed. The patients are able to track exercise history and receive historic feedback on the quality of the IWT session using the app. The feedback system

1
2
3
4
5
6
7
8
9 employs the on-board accelerometer of the phone and GPS system to assess intensity and
10 geographical location. Information on training intensity, total number of steps per day, IWT-
11 data and data from the standardised walking test is stored in the smartphone or iPod and
12 automatically transmitted to the central database at the Danish Strategic Research Centre for
13 Type 2 Diabetes (DD2) when connected to Wi-Fi or mobile data network.[16]

26 *Experimental intervention, phase one*

27
28 The patient receives a thorough introduction to the InterWalk app with follow-up
29 instructions. The introduction consists of information and test of the app and the patient can
30 ask clarifying questions if needed. A detailed manual regarding the InterWalk app is
31 extradited to each patient. The health professional provides technical guidance and helps the
32 patient to structure an everyday life with IWT during phase one. Patients are encouraged to
33 perform IWT using the InterWalk app (see section: InterWalk Walking Training using the
34 InterWalk Application) as a minimum three times per week, 30 to 60 minutes per session,
35 with two of the sessions taking place at the health promotion centre and the third is
36 conducted in the patient's everyday life environment. The aim is that all patients are capable
37 of continuing IWT using the InterWalk app at the end of phase one (Table 3).

Table 3, EXAMPLE OF EXPERIMENTAL INTERVENTION FOR ONE WEEK IN PHASE ONE

Weekday	Intervention at the Health promotion centre	Independent training in own environment	Notes to health professionals
<i>Monday</i>	Duration: 90 minutes 1. Warm-up: short walk in a group to the walking point (either a park or an area near the health promotion centre) 2. Interval Walking Training: every patient does Interval Walking Training with the InterWalk app for a minimum of 30 minutes. Every patient does the Interval Walking Training by themselves so that the app instructions during the session can be followed. The health professionals guide and facilitate the individual patient if necessary. After the Interval Walking Training everyone goes back to the health promotion centre 3. Group conversation at the health promotion centre after doing interval walking with all participating patients. Different focus areas are discussed in the group. Everyone sits on a chair and the health professional participates as a facilitators in the group conversation (examples of focus areas: weather conditions, motivation for exercise, social needs when waking, motivation for a physically active everyday life)		Remember to encourage and guide every patient to do Interval Walking Training three times a week either by themselves or together with other patients. Make sure that everyone are active during the walking sessions. If a patient needs to do a new walking test then it is the health professional who should help during the intervention period. Every patient need a new test every forth week.

Experimental intervention, phase two

In phase two patients in the experimental intervention group are randomly allocated into two follow-up conditions: with unsupervised Interval Walking Training without support (IWTgroup) or with motivational support (IWTsupport-group) following the intervention period until 52-week follow-up (see Figure 1).

Interval Walking Group without support (IWTgroup)

All patients in the Interval Walking Group (IWTgroup) are encouraged to continue to perform IWT with the InterWalk app three times a week, 30 to 60 minutes per session. The patients are not provided with any follow-up or support from health professionals from the end of the intervention period until follow-up at 52-weeks. However, patients are allowed to contact the health professionals at the health promotion centre at any time if necessary.

Interval Walking Group with support (IWTsupport-group)

Patients in the Interval Walking Group with support (IWTsupport-group) are also encouraged to do IWT with the InterWalk app three times per week. All patients in the IWTsupport-group receive additional motivational support by the health professionals at the promotion centre (see below for information regarding the motivational support).

Motivational support (phase two)

The motivational support is summarised in Table 4. The motivational intervention consists of four motivational interviews with individual goal setting and weekly Short Message

1
2
3
4
5
6
7
8
9 Service via the mobile phone (a SMS-track), (see Figure 5 and 6). Furthermore, patients
10 have the opportunity to participate in IWT at predefined timeslots with an Interval Walking
11 Ambassador in the local community near the health promotion centre (see Figure 1).
12
13

14
15 *Motivational interview and goal setting:* All health professionals from the
16 municipalities are well-educated in conducting the motivational interview with patients. All
17 health professionals working in a health promotion centre in Denmark are obligated to
18 participate in formalised motivational interviewing courses conducted by educators with
19 psychological background. The Motivational interview is a semi-structured interview used
20 to structure the communication between the patient and the health professional. The
21 interview works as a partnership where focused and detailed questions reveal and visualize
22 the patients motivation and barriers towards behaviour change and acknowledgement of
23 patient autonomy.[26] Four motivational interviews are scheduled for each patient in the
24 IWT support-group. See Table 4 for more detail. The motivational interview seek to help the
25 patients reflect on their physically active habits and to set individual motivating goals related
26 to everyday life.[27] The health professional secures all notes and reflections from the
27 interview in the InterWalk database. As more than one interview is conducted over the trial
28 period fidelity may be ensured when the health professional uses the patient's reflections
29 from the former interview to help reflect upon motivation and barriers towards changes in
30 the next motivational interview. The goal setting is based on the S.M.A.R.T.-principle
31 derived from the Goal Setting Theory developed by Edwin Locke.[28] S stands for Specific

(e.g. what do I want to accomplish?), M for Measurable (e.g. specific and measurable), A for achievable (realistic), R for relevant (individual goals) and T for timely (not too big to achieve in a short period).[29]

Table 4. MOTIVATIONAL INTERVIEWS WITH INDIVIDUAL GOAL SETTING

PHASE TWO, IWTsupport-group

<i>Four semi-structured motivational interviews with individual goal setting,</i>	<ul style="list-style-type: none"> ○ The interviews aim at helping the patient to reflect on why and how physical activity can be incorporated in everyday life ○ Make informed choices regarding behavioral changes regarding physical activity ○ Relate to own everyday life ○ Clarify barriers and facilitators of importance for the individual ○ Two to three individual goals are set at all interviews ○ The goals is based on need in the individual everyday life
---	--

A short resume with the individual goal setting is written after all interviews in the database. The written text is prospectively incorporated in the following interviews with the patient at the health promotion centre

The interviews are placed in Week 16, 20, 28, 40 post baseline-test. Goal setting in the interviews are based on the *the S.M.A.R.T.- principle derived from the Goal Setting Theory developed by Edwin Locke*. [28]

Short Message Service (henceforth referred to as text message) enables inexpensive and possibly effective interaction between patients and health professionals at any time or place.[30,31] Communication as well as feedback is believed to enhance motivation through feelings of competence and relatedness [32], which may positively affect adherence to treatment. Text messages have shown positive effect on various health outcomes including diabetes self-management when used in behavior change interventions. Further, a higher effectiveness and lower attrition rate has been observed when customized and tailored messages is used.[30] In the present study, the patient receives two types of text messages during phase two (see Figure 4 and 5). The first type is a weekly and interactive

1
2
3
4
5
6
7
8
9 text message consisting of questions regarding the amount of IWT performed during the past
10 week (see Figure 4). The patients are required to give feedback by returning a text message
11 with one of the three response options provided. If the patient does not reply for two
12 consecutive weeks, or if the patient answers that she/he has not been walking, a personal
13 phone call to the patient is conducted from a health professional from the local health
14 promotion centre. The aim of the call is to encourage and help the patient to plan IWT to fit
15 the individual life of the patient. The second type of text message is sent every fourth week,
16 encouraging the patients to perform the walking test using the InterWalk app without a
17 requirement of feedback (see Figure 5).

35 *Interval Walking Ambassadors:* Using peers to educate other patients with
36 T2D has shown effective in providing ongoing support over a longer period.[33,34] In this
37 study, volunteer patients with T2D are recruited through the Danish Diabetes Association,
38 where a consultant contacts possible patients via e-mail. The Interval Walking Ambassadors
39 do IWT locally in phase two with patients from the IWTsupport group. The Interval
40 Walking Ambassadors receives a two-day training programme in the participating
41 municipality by researchers from the InterWalk research group. At any time during phase

11 (see Table 2).

12 13 14 15 *Adherence to interventions*

16
17 To prevent patients from dropping out during phase one of the trial, patients are contacted
18
19 by phone by a trained health professional if they fail to appear at the planned training
20
21 sessions. Up to five attempts are made to contact the patient. In phase two only patients
22
23 allocated to the IWTsupport-group are monitored by SMS-track and supervised during the
24
25 phase until week 52. Patients in IWTgroup have no contact with the health professionals
26
27 until 52-weeks follow-up (see Figure 1).
28
29
30
31
32

33 *Control intervention – Standard care*

34
35 Patients in the control group receive the standard rehabilitation treatment offered to
36
37 patients with T2D in Denmark in a multimodal setting including physical activity (phase
38
39 one, Figure 1). The duration of rehabilitation treatment differs between participating
40
41 municipalities, but may not be shorter than eight weeks during phase one. At the end of the
42
43 standard care rehabilitation program in the municipalities there is no follow-up on the
44
45 exercise intervention, which is the normal procedure in Danish municipalities (phase two,
46
47 Figure 1).[35]

The participating municipalities offer group exercise twice a week at the health promotion centres with 6-15 patients participating depending on the population size in the participating municipality. The content of the group exercise period is based on clinical guidelines in Denmark. A typical session is structured with first a short warm-up session followed by a strength and cardio part and finished with a cool-down period with strengthening (See Table 2). Furthermore, it is recommended that the patients have regularly consultation at the general practitioner every third month.

Additional rehabilitation care (Co-interventions)

All patients receiving rehabilitation at either a health promotion centre or at the hospital receives an offer of specific disease related patient education, diet counselling and smoking cessation.[35] It is optional whether the patient participate in one or all additional offers.

Disease specific patient education includes a section focused on behaviour modification and self-management and a specific part on diseases were the patients get knowledge regarding sequelae. *Diet counselling* regarding nutritional advice when living with T2D is handled by a dietitian. *Smoking cessation* is either group based or in individual process and is handled by smoking cessation counsellors.

Previous studies have established that physical activity influences glycaemic control [36] and Karstoft and colleagues (2013) has shown that physical activity with Interval Walking Training had effect on glycaemic control in patients with T2D. [15] Moreover, medication and dietary interventions have also proven to improve glycaemic control and reduce disease related complications.[37–39] In the present trial the primary outcome focus on physical activity in relation to everyday life.

Data on the primary and secondary outcomes are obtained at baseline, post intervention (after 8-12 weeks) and 52 weeks after enrolment (Table 5). To standardize all measurements between health professionals and participating centres, all health professionals uses standardised protocols crafted for the trial regarding procedures and measurements. All data are entered directly in an online database (see section: Data management and quality control).

* Article 1: The effectiveness of smartphone delivered Interval Walking Training on moderate-and-vigorous physical activity versus standard care in patients with type 2 diabetes: a parallel group single-blinded randomized controlled trial.

†Article 2: Baseline characteristics and personality traits in patients with type 2 diabetes: descriptive study of all participants

‡Article 3: Nay Sayers – Characteristics of patients who does not want to be part of a physical activity study related to everyday life; all patients referred to the health promotion centre in the municipalities participating in the randomized controlled trial.

§Article 4: Effectiveness of smartphone delivered Interval Walking Training versus standard care in patients with type 2 diabetes on HbA1c and HDL, high-density lipoprotein; LDL, low-density lipoprotein: A sub-study to the randomized controlled trial (The InterWalk Trial, article 1), measured in a sub-sample (n=40).

Primary outcome

The primary outcome is change in moderate-to-vigorous-intensity physical activity from baseline to 52-week follow-up.

Secondary outcomes

The key secondary outcome changes in motivation for sustaining a behavioural change with physical activity in everyday life at 52-week follow-up.

Other secondary outcomes of interest are changes in patients' fitness level measured as VO₂-peak by the standardised walking test (part of the InterWalk application) and health-related quality of life. Strength in the lower extremities, adherence to intervention and impact of personality traits on physical activity in everyday life are also considered exploratory secondary outcomes. All outcomes are measured at baseline, after intervention and at 52-week follow-up (see Figure 2).

Data collection

Level of daily moderate-to-vigorous-intensity physical activity

It is important to gain knowledge into physical activity in everyday life. To determine level of daily moderate-to-vigorous-intensity physical activity a hip-mounted physical activity monitor (Axivity AX3, Newcastle, UK) is worn for seven consecutive days, at three time periods during the trial period; after baseline-test, after the intervention period and again at

1
2
3
4
5
6
7
8
9 52-weeks follow-up. The monitor is fixed using adhesive tape (Leukomed T, BSN medical,
10 Germany) on right side the lumbar spine. Additionally, a monitor is fixed on on the lateral
11 side of the right thigh (Leukomed T, BSN medical, Germany) for supporting information
12 about posture.[25] The patients are instructed not to remove the physical activity monitor at
13 any time during the three time periods. If de-attached, the participants are trained in fixing
14 the monitors correctly and are instructed to note the incident. If the patients need help in
15 fixing the monitors correctly the health professionals at the health promotion centre are
16 educated to help.

28 *Physical activity diary*

29
30 In order to validate the physical activity level during the seven days with physical activity
31 monitors we ask the patient to complete a seven-day diary to report number of work- and
32 sleep hours, bicycling and strength training sessions at the three time periods on a daily
33 basis. The physical activity monitor and the diary are returned free-of-charge via mail. The
34 patient is contacted by phone after within one week if the physical activity monitors are not
35 returned as expected.

5
6
7
8
9 (BREQ-2) which measures individual motivation for physical activity. The questionnaire
10 consists of 19 questions in a 0-4 Likert format.[40] In addition to the questionnaire, patients
11 are asked to answer four questions in a 0-4 Likert format, regarding motivation for physical
12 activity after being diagnosed with T2D.
13
14
15
16

17 18 19 20 *Health Related Quality of Life*

21 The patients Health Related Quality of Life is very important to maintain after being
22 diagnosed with T2D.[41] To gain knowledge into the individual perception of quality of life
23 on a physical and mental level we use the Short-Form Health Survey (SF-12). The
24 questionnaire consists of 12 questions and uses a Likert scale of 1-3 for the physical function
25 items; 1-5 for the bodily pain, social function, and general health perceptions items; 1-6 for
26 the vitality and mental health; and a dichotomous scale of yes/no for the presence of role
27 function limitations. The higher score, the higher level of health or functioning.[42]

32
33
34
35
36
37
38
39

40 *Maintenance of behaviour change with physical activity*

41 Automaticity of behaviour is essential when new habits become present in the everyday
42 life.[43] To measure if the patient has adopted new habits as a result of the intervention we
43 ask the patient to answer four questions from The Self-Report Habit Index. The Index uses a
44 0-4 Likert format and the four questions to be answered measures automatic activation,
45 frequency of behaviour and relevance to self-identity related to physical activity.[44]

56
57
58
59
60

VO₂-peak

VO₂-peak is measured by a validated and standardised walking test consisting of 5 stages incorporated in the InterWalk app; 1) 30 sec. of standing still, 2) 2 min. of slow walking 3) 2 min. of walking at moderate intensity 4) 2 min. walking at high intensity 5) 1 min. walking at highest intensity possible. The four paces are self-selected (See, Figure 3 and 4).[25] The test is performed with an iPod placed in the pocket at the hip and the instructions are delivered from the app through earphones. To ensure the right walking intensity in the intervention period, the patients are asked to perform the test every 4th week.[16]

Strength in the lower extremities

The sit-to-stand test (30 seconds) measures the lower body strength and will be administered using a chair without arms. The patient is encouraged to complete as many full stands as possible within a 30-sec time limit.[45]

Adherence to the intervention

Adherence is determined by an evaluation and quantification of the electronic log of data from the InterWalk app to the central database of all uploaded data.

The “Recent Physical Activity Questionnaire” (RPAQ) has 9 main questions, which covers 4 domains of physical activity: domestic life, work, recreation and transport. Physical Activity is estimated in MET’s (Metabolic Equivalent). In answering the questions in the questionnaire, the patient will answer in regards to the last four weeks with physical activity in the everyday life.[46]

Personality traits

The NEO-Five Factor Inventory (NEO-FFI) [47] consists of 60 questions in a 0-4 Likert format constructed by selecting 2 items from each of the six facets characterizing each of the five personality traits (Neuroticism, Extraversion, Openness, Agreeableness, Conscientiousness) assessed by NEO-PI-R. The Sensation Seeking Scale (SES) [48] is a 40 items self-administered questionnaire consisting of 40 questions designed to test the tendency towards varied, novel and intense sensations.

Demographic, social economic and anthropometry measures

Information on height, weight, waist and hip circumference is collected before inclusion through an electronic questionnaire at the first formal meeting at the health promotion centre and after the intervention period and again at 52-week follow-up. Waist circumference is measured at the point between the top of the iliac crest and the bottom of the costae regardless of the placement of the umbilicus. A Tanita stadiometer is used to measure height

1
2
3
4
5
6
7
8
9 and an electronic weight to measure weight. Data on self-reported information together with
10 relevant national registers will be used to obtain information regarding hospitalization, co-
11 morbidities, medical history, use of medicine and mortality.
12

13
14
15 *Height* measurement is conducted using a portable altimeter (Tanita
16 Stadiometer). The measurement is done without shoes and is repeated two times with each
17 measure to nearest 0,1 cm. If the two measures are dissimilar with more than 0,5 cm, then
18 the measurement is repeated. *Weigh* is measured in kilograms (kg) using an electronic
19 weight. The measure is repeated two times with each measure to nearest 0,1 cm. If the two
20 measures are dissimilar with more than 0,5 kg, then the measurement is repeated a third
21 time. The patient is weighed fully dressed and one kilo is subtracted from each measure.
22
23 *Hip circumference* is measured on the skin on the crest of the hipbone. The patient is asked
24 to place a finger in the belly bottom and the measure is done with a tape measure (2
25 meters) placed on the upper side of the patients' finger. If the two measures are dissimilar
26 with more than 0,5 cm, then the measurement is repeated a third time.

9 promotion centres, during the trial period. In case of severe adverse events, the Scientific
10 Ethical Committee of the Capital Region of Denmark is informed.
11
12

13 14 15 **Sample size considerations** 16

17 The minimum difference of interest (MDI) is 10 minutes per day. Based on existing
18 experimental evidence, we expect the standard deviation (SD) of the change in moderate-
19 and-vigorous physical activity from baseline to 12 month follow up to be between 1.2 – 2.3
20 times the effect size.[49,50] Therefore, SD twice the MDI (20 min of moderate-and-
21 vigorous physical activity) per day was applied in the sample size calculations. After
22 applying Bonferroni adjustment due to multiple comparisons in the three group trial a total
23 of 190 participants are needed to obtain a statistical power (1- β) of 80% with an α of 0.017
24 (two-tailed). Allowing for an attrition rate of 30%, 272 patients (91 in the control group
25 and 181 in experimental group) are recruited. The setting enables recruitment until
26 December 15st 2016. The sample size is truncated at 272 participants or the N reached at
27 the end of recruitment period - whatever is reached first (see section 'Participants').

9 the post intervention test (phase two). A health professional associated with the trial,
10 telephones the patient and inform about random allocation after returning the PA monitors to
11 either IWT-group or IWTsupport-group. The patients are stratified by gender to ensure an
12 equal number across all groups. The allocation sequence is generated through a standardised
13 computer program by an independent researcher (RC). The allocation sequence is concealed
14 until the trial arms are assigned. A Flow of patients is depicted in Figure 2.
15
16
17
18
19
20
21
22

23 **Blinding**

24
25 The scientific staff is blinded to patient allocation from baseline to the 52-week follow-up is
26 completed for all patients. The health professionals at the promotion centre are not blinded
27 to allocation to either standard care or experimental groups.
28
29
30
31
32
33

34 **Statistical methods**

35
36 All analyses will be conducted according to the Intention-To-Treat principle. Continuous
37 endpoints will be analysed using repeated measures analysis of covariance in a mixed
38 linear model. Categorical and dichotomous end points will be analysed with the use of
39 logistic regression. The model will include with group, and sex as fixed effects, with the
40 baseline value as a covariate.
41
42
43
44
45
46
47

48 All patients randomised to one treatment, will be analysed according to the treatment to
49 which the patient was allocated, irrespective of whether they received this or some other
50 treatment, or no treatment at all. The ITT population will be handled all patients randomised

to the three treatment arms, and the dataset is equal to the “all patients randomized set” (APRS). Missing values due to patients’ absence from follow-ups or withdrawal from the study are to be expected in clinical trials. Several approaches are described for handling missing data in the ITT analysis, and among them “baseline observation carried forward” (BOCF: i.e., a null-responder imputation, where the level at baseline is also considered the last). A linear mixed model analysis includes all patients with a baseline assessment, and includes both fixed and random factors. Thus, repeated linear mixed model method is chosen for the primary analyses in this trial (i.e., no data imputation), whereas the BOCF imputation, as well as the ‘Per Protocol’ population will be applied for the purpose of sensitivity analysis. Also, we will explore whether potentially important covariates such as age, sex, disease duration, degree of overweight (using BMI), and smoking status at enrollment/baseline could potentially confound the results from the primary analyses (i.e. an extra pre-specified sensitivity analysis). Exploratory analyses of the treatment effects will be performed on some the secondary outcomes.

Data management and quality control

All data are entered in an SSL-secured, online-based database developed by the Danish Stakeholder Help2Run (CVR: 34801088). The online-based database logistically handles the data gathered at baseline, after intervention in phase one, and during follow-up (phase two) and after 52 weeks. Data on demography, measurements, tests and questionnaires are

1

9 entered directly in the database available via a project-specific
10 homepage ([http://www.runsafe.dk/mtd/login/admin-](http://www.runsafe.dk/mtd/login/admin-signi)
11 [https://www.runsafe.dk/mtd/login/admin-](https://www.runsafe.dk/mtd/login/admin-signin)
12 [signihttps://www.runsafe.dk/mtd/login/admin-signin](https://www.runsafe.dk/mtd/login/admin-signin)). A protected back-end system
13 (<https://www.runsafe.dk/mtd/admin>) is used to logistically handle information on
14 demography, measurements, tests and questionnaires on each participant in the trial (for
15 information on Interval Walking Training using the InterWalk app see '*Interval Walking*
16 *Training using The InterWalk Application*'). The system was approved in 2014 after an
17 inspection by the Danish Data Protection Agency. Access to personalized data from
18 the InterWalk participants is only possible using a personalized username and password.
19 Only specified researchers are allowed to administrate the back-end system and each
20 researcher and project member with access to the back-end has a unique username and
21 personal password for the back-end system. All activities, including changing data and
22 downloading data, in the back-end system are logged in accordance with the rules and
23 regulations from the Danish Data Protection Agency. A unique subject ID number will be
24 subscribed to all patients in order to anonymize data. The identification key (ID to personal
25 information) will be encrypted and stored securely and separately from the unique ID
26 number on a secure database.

Ethics and Dissemination

48
49
50 The InterWalk trial contributes with important knowledge on different treatment approaches
51 in the rehabilitation of patients with T2D. Physical activity and exercise have beneficial
52
53

6
7
8
9 effect on patients with T2D when the interventions are conducted in well-designed efficacy
10 studies.[2,4,6] However, little is known on whether this effect also is present in effectiveness
11 studies or “real-world setting” studies. These studies are of great importance and relevance
12 regarding evidence-based medicine highlighting the importance of the InterWalk trial.
13
14

15
16
17 The InterWalk trial has a pragmatic design that allows for different
18 intervention periods in the participating municipalities. Furthermore, the interventions are
19 conducted directly in the clinical setting giving a more reliable frame of the experienced
20 challenges in a population with T2D. We believe that the implementation of the study results
21 will have a smoother implementation phase, as the health professionals already are familiar
22 with the preceding’s.
23
24
25
26
27
28
29

30
31 The trial gives valuable insight into the impact of different motivational and
32 supportive tools as well as knowledge about individual motivation and the impact on
33 sustaining a newly acquired behaviour change regarding physical activity in everyday life.
34
35
36

37 Interval Walking Training is expected to be a suitable and effective way of
38 providing moderate-vigorous physical activity for at large group of patients with T2D. IWT
39 can be done at any time and anywhere and is thus integrated and tailored to fit individual
40 everyday life. The overall objective is to promote lifelong physical activity for the individual
41 and we believe that experiences from the present trial can help when planning future
42 interventions with IWT to patients with various lifestyle diseases e.g. coronary heart
43 diseases.

It is a major advantage that the trial is designed as a randomised controlled trial in a “real-world setting” with a study population representing patients with T2D referred to rehabilitation. Furthermore, data and results are collected consecutively and directly in the clinical setting in which the interventions are to be used after the trial. Together with the very limited number of inclusion and exclusion criteria and a stratification of patients on gender secures external validity of the trial and thus will add important information to the current body of evidence on T2D treatment.

All data from eHealth solutions as the InterWalk app are electronically monitored. The patient is not dependent on opening hours at the health promotion centre as the InterWalk is either installed on an iPhone or an iPod. This gives a unique possibility for the patient to be physically active whenever it fits in their everyday life.

We acknowledge that physical activity only has effect when adherence is high, which is why we first compare standard care with interval walking for a shorter period (phase one) followed by a re-allocation of patients in the experimental group to either interval walking with or without motivational support (phase two). All groups have a 52-week follow-up. The trial design enables us to investigate if patients are able to maintain a newly acquired behaviour change with physical activity in everyday life with or without motivational support for a longer period.

All personalized data and measures are stored on a central online-based database developed to logistically handle all data collected at baseline and during follow-

Effect of Interval walking on type 2 diabetics

6
7
8
9 up. The backend system (<https://www.runsafe.dk/mtd/admin/>) secures all information
10 from each patient. The construction of the database with personalized usernames,
11 passwords, and specific permissions to all health professionals and administering
12 permissions to scientific staff in the backend secures all data. Furthermore, all activities are
13 logged.
14
15
16
17
18

19 All outcomes measures are assessed blinded to allocation at baseline and the
20 primary outcome is assessed blinded to intervention in the experimental group after the
21 intervention period. All measures are conducted by the health professionals at the health
22 promotion centres and are blinded for allocation after intervention in the experimental group
23 with IWT until after return of the physical activity monitors by the patient. All statistical
24 analyses are blinded to researchers, reducing the risk of detection and interpretation
25 bias.[51–53] All secondary outcomes, but VO₂-peak and the Sit to Stand Test are self-
26 reported and by nature likely to be biased. The patients answer questionnaires independently
27 of the health professionals at the health promotion centres.
28
29
30
31
32
33
34
35
36
37
38

39 The secondary outcomes of motivation for physical activity and behaviour
40 change are of highly importance as knowledge concerning motivational support and
41 maintenance of effect (new habits with physical activity) to our knowledge is lacking in
42 patients with T2D. This knowledge will help health professionals to better tailor the
43 treatment and herby potentially achieve a higher adherence to the programme following the
44 supervised intervention.

6
7
8
9 The limitations in this trial are similar to those of other exercise trials where
10 physical testing and time-of-day and day-to-day variation constitute a challenge. We have
11 standardised all testing protocols for all procedures to reduce the variation and run a
12 routine program of on-going calibration and training of the health professionals.
13
14
15
16

17 The trial is conducted in accordance with the Helsinki Declaration II.[54] All
18 eligible patients receive written and oral informed consent prior to inclusion before any
19 additional trial procedures. Data on all screened patients are registered in order to report
20 characteristics of in-eligible patients and written informed consent is also obtained from
21 these patients. The patients can withdraw from the trial at all times during the trial period.
22 This has no consequence for any other future treatment. If patients discontinue the trial
23 intervention, standard care is offered for the rest of the intervention period. All results from
24 the trial, negative, positive or inconclusive results, are disseminated in international peer-
25 reviewed scientific papers and at national and international conferences. We follow the
26 guidelines from the International Committee of Medical Journal Editors when authorship is
27 determined. The results will be reported when all long-term data become accessible.

FIGURE LEGENDS**Figure 1.** Timeline and overview of interventions in the InterWalk trial

Phase one shows baseline-test, randomization, intervention and test after intervention. Phase two shows the re-allocation of patients in the experimental group who do Interval Walking Training (IWT with the InterWalk app to either IWT with or without motivational support form a health professional. All patients are tested at baseline, after intervention and again at follow-up at 52 weeks

To BMJ Open

As the senior author of the published paper "*Implementation of interval walking training in patients with type 2 diabetes in Denmark: rationale, design, and baseline characteristics*" I hereby approve the use figure A, B and C in paper "*The long-term effect of smartphone-delivered Interval Walking Training on physical activity in patients with type 2 diabetes: protocol for a parallel group single-blinded randomized controlled trial*" submitted to BMJ Open by Laura Valentiner.

Original publication of the figures:

"*Implementation of interval walking training in patients with type 2 diabetes in Denmark: rationale, design, and baseline characteristics*. Ried-Larsen M, Thomsen RW, Berencsi K, Brinkløv CF, Brøns C, Valentiner LS, Karstoft K, Langberg H, Vaag AA, Pedersen BK, Nielsen JS. Clin Epidemiol. 2016 Jun 8;8:201-9. doi: 10.2147/CLEP.S97303. eCollection 2016."

Kind regards

PhD Jens Steen Nielsen

2016-08-17

STANDARD PROTOCOL ITEMS: RECOMMENDATIONS FOR INTERVENTIONAL TRIALS

SPIRIT 2013 Checklist: Recommended items to address in a clinical trial protocol and related documents*

Section/item	Item No	Description	Page
Administrative information			
Title	1	Descriptive title identifying the study design, population, interventions, and, if applicable, trial acronym	1
Trial registration	2a	Trial identifier and registry name. If not yet registered, name of intended registry	5 & 11
	2b	All items from the World Health Organization Trial Registration Data Set	N/A
Protocol version	3	Date and version identifier	N/A
Funding	4	Sources and types of financial, material, and other support	44-45
Roles and responsibilities	5a	Names, affiliations, and roles of protocol contributors	1-3 & 44
	5b	Name and contact information for the trial sponsor	N/A
	5c	Role of study sponsor and funders, if any, in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication, including whether they will have ultimate authority over any of these activities	N/A
	5d	Composition, roles, and responsibilities of the coordinating centre, steering committee, endpoint adjudication committee, data management team, and other individuals or groups overseeing the trial, if applicable (see Item 21a for data monitoring committee)	10-11, 13-14, 17-20, 22, 24-27, 35-38
Introduction			
Background and rationale	6a	Description of research question and justification for undertaking the trial, including summary of relevant studies (published and unpublished) examining benefits and harms for each intervention	4, 7-9
	6b	Explanation for choice of comparators	7-9, 13-14, 17-18, 21-26
Objectives	7	Specific objectives or hypotheses	9
Trial design	8	Description of trial design including type of trial (eg, parallel group, crossover, factorial, single group), allocation ratio, and framework (eg, superiority, equivalence, noninferiority, exploratory)	9-11
Methods: Participants, interventions, and outcomes			
Study setting	9	Description of study settings (eg, community clinic, academic hospital) and list of countries where data will be collected. Reference to where list of study sites can be obtained	10-11

1				
2	Eligibility criteria	10	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will perform the interventions (eg, surgeons, psychotherapists)	11-13
3				
4				
5	Interventions	11a	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	13-26
6				
7				
8				
9		11b	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving/worsening disease)	N/A
10				
11				
12		11c	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return, laboratory tests)	13-26
13				
14				
15		11d	Relevant concomitant care and interventions that are permitted or prohibited during the trial	26
16				
17	Outcomes	12	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	30-35
18				
19				
20				
21				
22				
23	Participant timeline	13	Time schedule of enrolment, interventions (including any run-ins and washouts), assessments, and visits for participants. A schematic diagram is highly recommended (see Figure)	4, 9-10, 14, 26-30
24				
25				
26	Sample size	14	Estimated number of participants needed to achieve study objectives and how it was determined, including clinical and statistical assumptions supporting any sample size calculations	5, 36
27				
28				
29				
30				
31	Recruitment	15	Strategies for achieving adequate participant enrolment to reach target sample size	10-12
32				
33	Methods: Assignment of interventions (for controlled trials)			
34				
35	Allocation:			
36				
37	Sequence generation	16a	Method of generating the allocation sequence (eg, computer-generated random numbers), and list of any factors for stratification. To reduce predictability of a random sequence, details of any planned restriction (eg, blocking) should be provided in a separate document that is unavailable to those who enrol participants or assign interventions	27-28
38				
39				
40				
41				
42				
43	Allocation concealment mechanism	16b	Mechanism of implementing the allocation sequence (eg, central telephone; sequentially numbered, opaque, sealed envelopes), describing any steps to conceal the sequence until interventions are assigned	36-37
44				
45				
46				
47	Implementation	16c	Who will generate the allocation sequence, who will enrol participants, and who will assign participants to interventions	36-38
48				
49				
50				
51				
52				
53	Blinding (masking)	17a	Who will be blinded after assignment to interventions (eg, trial participants, care providers, outcome assessors, data analysts), and how	37
54				
55				
56				
57		17b	If blinded, circumstances under which unblinding is permissible, and procedure for revealing a participant's allocated intervention during the trial	N/A
58				
59				
60	Methods: Data collection, management, and analysis			

1				
2	Data collection methods	18a	Plans for assessment and collection of outcome, baseline, and other trial data, including any related processes to promote data quality (eg, duplicate measurements, training of assessors) and a description of study instruments (eg, questionnaires, laboratory tests) along with their reliability and validity, if known. Reference to where data collection forms can be found, if not in the protocol	13-14, 26-35
3				
4				
5				
6				
7				
8				
9		18b	Plans to promote participant retention and complete follow-up, including list of any outcome data to be collected for participants who discontinue or deviate from intervention protocols	13-26
10				
11	Data management	19	Plans for data entry, coding, security, and storage, including any related processes to promote data quality (eg, double data entry; range checks for data values). Reference to where details of data management procedures can be found, if not in the protocol	38-39
12				
13				
14				
15	Statistical methods	20a	Statistical methods for analysing primary and secondary outcomes. Reference to where other details of the statistical analysis plan can be found, if not in the protocol	37-38
16				
17		20b	Methods for any additional analyses (eg, subgroup and adjusted analyses)	37-38
18				
19		20c	Definition of analysis population relating to protocol non-adherence (eg, as randomised analysis), and any statistical methods to handle missing data (eg, multiple imputation)	38
20				
21				
22				
23				
24				
25				
26	Methods: Monitoring			
27				
28	Data monitoring	21a	Composition of data monitoring committee (DMC); summary of its role and reporting structure; statement of whether it is independent from the sponsor and competing interests; and reference to where further details about its charter can be found, if not in the protocol. Alternatively, an explanation of why a DMC is not needed	N/A
29				
30		21b	Description of any interim analyses and stopping guidelines, including who will have access to these interim results and make the final decision to terminate the trial	N/A
31				
32				
33				
34				
35				
36	Harms	22	Plans for collecting, assessing, reporting, and managing solicited and spontaneously reported adverse events and other unintended effects of trial interventions or trial conduct	N/A
37				
38				
39				
40	Auditing	23	Frequency and procedures for auditing trial conduct, if any, and whether the process will be independent from investigators and the sponsor	N/A
41				
42				
43	Ethics and dissemination			
44				
45	Research ethics approval	24	Plans for seeking research ethics committee/institutional review board (REC/IRB) approval	5, 11
46				
47	Protocol amendments	25	Plans for communicating important protocol modifications (eg, changes to eligibility criteria, outcomes, analyses) to relevant parties (eg, investigators, REC/IRBs, trial participants, trial registries, journals, regulators)	N/A
48				
49				
50				
51				
52	Consent or assent	26a	Who will obtain informed consent or assent from potential trial participants or authorised surrogates, and how (see Item 32)	11-13
53				
54		26b	Additional consent provisions for collection and use of participant data and biological specimens in ancillary studies, if applicable	N/A
55				
56				
57				
58	Confidentiality	27	How personal information about potential and enrolled participants will be collected, shared, and maintained in order to protect confidentiality before, during, and after the trial	38-39
59				
60				

1				
2	Declaration of interests	28	Financial and other competing interests for principal investigators for the overall trial and each study site	45
3				
4				
5	Access to data	29	Statement of who will have access to the final trial dataset, and disclosure of contractual agreements that limit such access for investigators	44-45
6				
7				
8				
9	Ancillary and post-trial care	30	Provisions, if any, for ancillary and post-trial care, and for compensation to those who suffer harm from trial participation	N/A
10				
11	Dissemination policy	31a	Plans for investigators and sponsor to communicate trial results to participants, healthcare professionals, the public, and other relevant groups (eg, via publication, reporting in results databases, or other data sharing arrangements), including any publication restrictions	43
12				
13				
14				
15				
16		31b	Authorship eligibility guidelines and any intended use of professional writers	44
17				
18		31c	Plans, if any, for granting public access to the full protocol, participant-level dataset, and statistical code	N/A
19				
20				
21				
22	Appendices			
23				
24	Informed consent materials	32	Model consent form and other related documentation given to participants and authorised surrogates	N/A
25				
26				
27	Biological specimens	33	Plans for collection, laboratory evaluation, and storage of biological specimens for genetic or molecular analysis in the current trial and for future use in ancillary studies, if applicable	N/A
28				
29				

*It is strongly recommended that this checklist be read in conjunction with the SPIRIT 2013 Explanation & Elaboration for important clarification on the items. Amendments to the protocol should be tracked and dated. The SPIRIT checklist is copyrighted by the SPIRIT Group under the Creative Commons "[Attribution-NonCommercial-NoDerivs 3.0 Unported](https://creativecommons.org/licenses/by-nc-nd/3.0/)" license.
