

SUPPLEMENTARY MATERIAL

Figure S1. Gene structure of wildtype *maa-1* (C18D11.2), *maa-1(sv38)* and *maa-1(ok2033)* deletion alleles.

Figure S2. Loss of *maa-1* increases resistance to stress. Repetition of the experiments shown in Figure 2C, D. (A-B) *maa-1* RNAi increases resistance to paralysis induced by aggregation of a 35-residue polyglutamine repeat protein (A) or human β -amyloid (B) ($P < 0.0001$ for both A and B). P values were calculated using the log-rank (Mantel-Cox) method.

Figure S3. Hypodermal downregulation of *maa-1* does not extend lifespan. Lifespan of *rde-1(ne219)* mutants in which *rde-1* expression is restored in the hypodermis using the *wrt-2* promoter; animals were subjected to control or *maa-1* RNAi ($P = 0.4960$). P values were calculated using the log-rank (Mantel-Cox) method. Replicate experiments and statistical analysis are shown in Table S1 and S2.

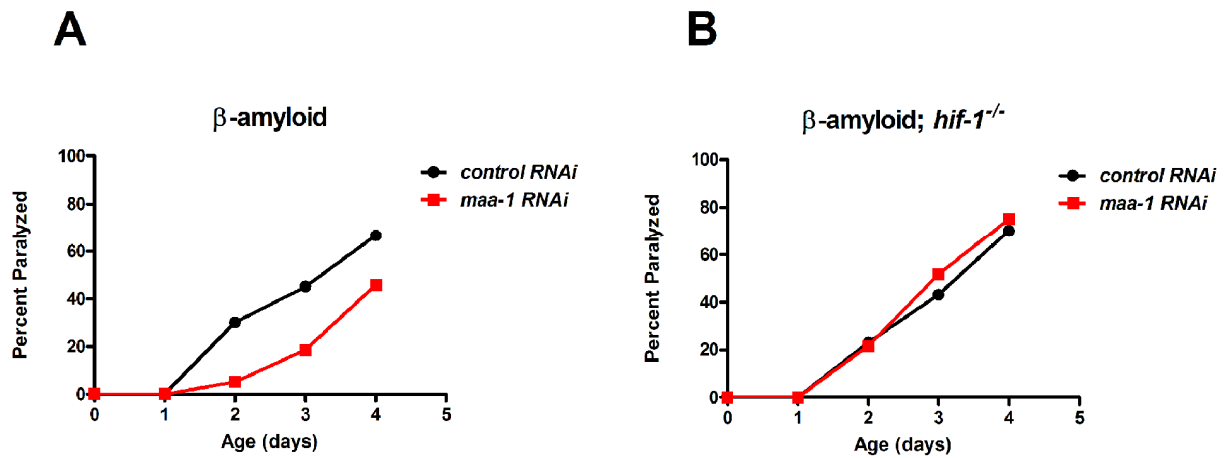

Figure S4. HIF-1 mediates the effect of loss of *maa-1* on proteotoxic stress. (A) *maa-1* RNAi increases resistance to paralysis induced by aggregation of human β -amyloid ($P < 0.0001$). (B) The effect is absent in transgenic animals lacking *hif-1*. P values were calculated using the log-rank (Mantel-Cox) method.

Figure S5. DAF-16 nuclear localization and transcriptional activity are not affected by loss of *maa-1*. (A) Localization of DAF-16 in wildtype and *maa-1(ok2033)* mutants expressing a *daf-16::GFP* transgene. Animals were incubated at 20°C (left panels) and at 37°C (right panels). (B) qPCR of *sod-3* expression in wild-type and *maa-1(ok2033)* mutants.

Figure S6. Total lipid content is not affected by loss of *maa-1*. Visualization of whole worm total lipid content by Oil Red O staining of wildtype and *maa-1(ok2033)* mutants. Representative pictures are shown in the left panels, and quantification of staining by optical density is shown in the right graph.

Figure S7. Loss of MAA-1 does not substantially affect total fatty acid content. Quantification of fatty acids in wild-type and *maa-1(ok2033)* animals obtained by gas chromatography. Error bars show the standard deviation from three samples obtained from independent preparations.

Figure S8. Loss of *maa-1* does not activate the UPR^{ER}. Percentage of worms reaching adulthood after 72 h of development from eggs laid on plates containing OP50 bacteria and tunicamycin (3 µg/ml).

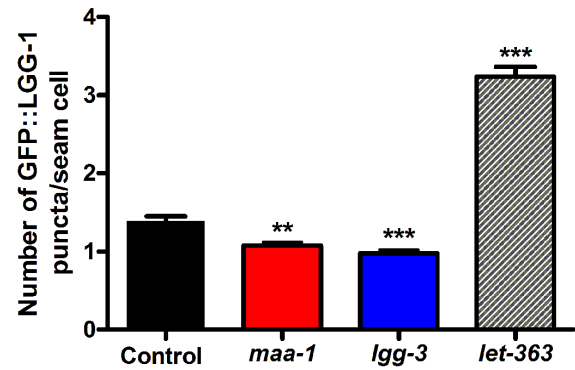

Figure S9. Autophagy is reduced in response to *maa-1* downregulation. Quantification of LGG-1::GFP punctae per seam cell of wildtype *C. elegans* subjected to control, *maa-1*, *lgg-3* (essential for autophagy), or *let-363* (*CeTOR*) RNAi (one-way ANOVA: *P<0.05, **P<0.001 vs control RNAi).

Table S1. Summary of adult lifespan data presented in this work.

Strain /Treatment	Maximum Lifespan	Mean Lifespan ± SE (days)	Number of worms (N)	Change (mean lifespan)	P-Value vs control	Figure in text
WT/control RNAi	31	20.36 ± 0.51	103			1A
