

Figure S4. Concentration of a) soluble sugars and b) starch in the basal section of the stem of three Maritime pine populations (Coastal-Galicia, Soria-Burgos and Morocco). Weevils were allowed to feed on the plants for 6 days. Bars are overall means ( $\pm$  S.E) across the four light and the two herbivory treatments (N = 36). Different letters above the bars denote significant differences ( $p < 0.05$ ) among populations.
