Physiologically-Based Pharmacokinetic Modeling for Predicting the Effect of Intrinsic and Extrinsic Factors on Darunavir or Lopinavir Exposure Co-administered with Ritonavir

Christian Wagner, Ph.D.<sup>a,d</sup>, Ping Zhao, Ph.D.<sup>b</sup>, Vikram Arya, Ph.D., FCP<sup>a</sup>, Charu Mullick, M.D.<sup>c</sup>, Kimberly Struble, Pharm.D.<sup>c</sup>, Stanley Au, Pharm.D., BCPS<sup>a</sup>

**Supplemental Table 1 (S1).** PBPK model input parameters for LPV, DRV, and RTV.

Parameter	LPV	DRV	RTV <sup>10</sup>
MW	628.8 <sup>1</sup>	547.7 <sup>2</sup>	721.0
Log P	4.2 (pred <sup>A</sup> )	2.5 <sup>3</sup>	3.9
pKa	Neutral <sup>1</sup>	Neutral <sup>B,4</sup>	1.8 (b); 2.8 (b)
fu	0.01 <sup>1</sup>	0.05 <sup>2</sup>	0.02
B/P	0.75 (pred <sup>C</sup> )	0.65 <sup>D,5</sup>	0.58
<b>Absorption</b>			
fa	1 <sup>E,6</sup>	1 <sup>E,2</sup>	1
[1/h]	0.57 <sup>7</sup>	1.04 <sup>8</sup>	0.22
<b>Distribution</b>			
PBPK model	minimal	minimal	minimal
Vss [L/kg]	0.82 (pred <sup>C</sup> )	1.7 <sup>F,9</sup>	0.40 (pred)
Kp scalar	0.098 <sup>G</sup>	1 (default)	0.048
<b>Elimination</b>			
CYP2D6			Vmax: 0.7; Km: 1
CYP3A4	CLint: 93.4 <sup>H</sup>	CLint: 182 <sup>I</sup>	Vmax: 1.37; Km: 0.07

CYP3A5			Vmax: 1; Km: 0.05
CLr	0.15 <sup>6</sup>	0.30 <sup>1</sup>	0.27
Additional CL		Systemic: 6.5 L/h <sup>1</sup>	HLM: 50

### Interaction - Inhibition

CYP2B6		Ki: 500 <sup>2</sup>	Ki: 1.3
CYP2C9		Ki: 52 <sup>2</sup>	Ki: 1.22
CYP2C19		Ki: 25 <sup>2</sup>	
CYP2D6		Ki: 41 <sup>2</sup>	Ki: 0.06
CYP3A4	Kapp: 0.41; Kinact: 1 <sup>J</sup>	Ki: 0.4 <sup>2</sup>	Kapp: 0.25; Kinact: 19.8
CYP3A5	Kapp: 1; Kinact: 1 <sup>J</sup>	Ki: 0.4 <sup>2</sup>	Kapp: 0.25; Kinact: 19.8

### Interaction - Induction

CYP3A4			Indmax: 68.5; IndC50: 1
CYP3A5			Indmax: 68.5; IndC50: 1

*B* base/basic, *B/P* blood:plasma partition ratio, *CL* clearance, *CL<sub>int</sub>* intrinsic clearance [ $\mu\text{L}/\text{min}/\text{mg}$  protein], *CL<sub>r</sub>* renal clearance [ $\text{L}/\text{h}$ ], *CYP* cytochrome P450, *DRV* darunavir, *fa* fraction absorbed, *fu* fraction of unbound drug in plasma, *HLM* human liver microsomes, *IndC50* inducer concentration that yields half-maximal induction [ $\mu\text{mol}/\text{L}$ ], *Indmax* maximum fold induction, *ka* absorption rate constant [ $\text{h}^{-1}$ ], *Kapp* concentration of mechanism-based inhibitor associated with half-maximal inactivation rate [ $\mu\text{mol}/\text{L}$ ], *Ki* inhibitor concentration that yields half-maximal inhibition [ $\mu\text{mol}/\text{L}$ ], *Kinact* inactivation rate of given enzyme [ $\text{h}^{-1}$ ], *Km* Michaelis-Menten constant [ $\mu\text{mol}/\text{L}$ ], *Kp* partition coefficient, *log P* logarithm of octanol-water partition coefficient, *LPV* lopinavir, *MW* molecular weight [ $\text{g}/\text{mol}$ ], *PBPK* physiologically-based pharmacokinetic, *pKa* negative decadal logarithm of acid dissociation constant, *pred* predicted, *RTV* ritonavir, *Vmax* maximum rate of metabolite formation [ $\text{pmol}/\text{min}/\text{mg}$  microsomal protein], *Vss* volume of distribution at steady state [ $\text{L}/\text{kg}$ ]

1  
2  
3  
4 A GastroPlus™ (v.8) prediction, based on the molecular structure of lopinavir.  
5  
6

7 B pKa of 2.4 (basic) and 13.6 (acidic) indicates the molecule is not ionized at the physiologically  
8 relevant pH range  
9  
10

11  
12 C Simcyp® prediction, based on the physicochemical properties of the drug.  
13  
14

15  
16 D Based on range of mean blood to plasma concentration ratio of total radioactivity ranging from  
17 0.59 to 0.70 with darunavir/ritonavir  
18

19  
20 E Based on absolute darunavir/ritonavir bioavailability of 82% and 20% of oral lopinavir  
21 recovered unchanged in the feces.  
22  
23

24  
25 F The V<sub>ss</sub> predicted from the physicochemical properties of DRV (0.7 L/kg) over-predicted  
26 boosted DRV C<sub>max</sub>, and underpredicted C<sub>min</sub>. Therefore, a V<sub>ss</sub> of 1.7 L/kg, which derives from  
27 intravenous administration of boosted DRV<sup>9</sup>, was applied to the model.  
28  
29  
30

31  
32 G The Parameter Estimation Tool provided within the software was used to fit the K<sub>p</sub> scalar to  
33 observed data following oral administration of 400 mg of unboosted LPV<sup>1</sup>.  
34  
35  
36

37  
38 H Calculated from the observed apparent clearance following oral administration of single doses  
39 of 400 mg and 800 mg of unboosted LPV<sup>1</sup>. The intrinsic clearance LPV was calculated using  
40 Simcyp®'s retrograde model.  
41  
42  
43

44  
45 I Clearance of unboosted DRV was described using data based on intravenous infusion of 150  
46 mg unboosted DRV<sup>2</sup>. From a variety of CYP enzymes, only CYP3A4 shows activity towards  
47 DRV<sup>2</sup>. Therefore, initially, based on minimal real clearance<sup>2</sup>, we assigned 98.8% of total drug  
48 elimination to CYP3A4, and 1.2% to renal elimination.  
49  
50  
51

52  
53 Preliminary simulations using this model showed an approximately 10-fold over-prediction of the  
54 effect of RTV on the exposure of DRV (data not shown). Subsequent refinement of the DRV  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 PBPK model, compared with the multiple dose pharmacokinetics of boosted DRV and DRV-  
5  
6 ketoconazole interaction data<sup>11</sup>, included a stepwise reduction of the fm (CYP3A4) from 98.8%  
7  
8 (initial PBPK model) to 85%, 80%, 75%, 70%, and 60%, with additional non-CYP clearances of  
9  
10 0%, 13.8%, 18.8%, 23.8%, 28.8%, and 38.8%. For all these DRV PBPK models, renal  
11  
12 elimination accounted for 1.2% of total elimination (see note 5).  
13  
14

15  
16 The DRV PBPK model constituting of a fm (CYP3A4) of 75% (182  $\mu\text{L}/\text{min}/\text{mg}$  protein), an  
17  
18 additional non-CYP clearance of 23.8% (6.5 L/h), and a renal clearance of 1.2% (0.3 L/h),  
19  
20 yielded best simulation results, and was subsequently used for all further simulations.  
21  
22

23 J Considering mechanism-based inhibition of CYP3A4 ( $K_{\text{app}} = 0.41 \mu\text{mol}/\text{L}$ ;  $k_{\text{inact}} = 6 \text{ h}^{-1}$ ) and  
24  
25 CYP3A5 ( $K_{\text{app}} = 1 \mu\text{mol}/\text{L}$ ;  $k_{\text{inact}} = 3 \text{ h}^{-1}$ ) by unboosted LPV<sup>12</sup> yielded predicted LPV steady-  
26  
27 state plasma concentrations exceeding those of boosted LPV (data not shown). To account for  
28  
29 the obvious over-prediction of mechanism-based inhibition by recombinant CYP3A4 and  
30  
31 CYP3A5, and since no other data are available, the inhibition potency of unboosted LPV was  
32  
33 “arbitrarily” decreased in a stepwise manner, with  $k_{\text{inact}}$  values of  $6 \text{ h}^{-1}$  (initial value)<sup>12</sup>,  $4 \text{ h}^{-1}$ ,  
34  
35  $2 \text{ h}^{-1}$ ,  $1 \text{ h}^{-1}$ , and  $0.5 \text{ h}^{-1}$  for both CYP3A4 and CYP3A5. Between  $k_{\text{inact}}$  values of  $4 \text{ h}^{-1}$  and  $2 \text{ h}^{-1}$ ,  
36  
37 the model was very sensitive, and the predicted oral clearance of LPV under steady state  
38  
39 conditions was increased markedly. However, at  $k_{\text{inact}}$  values of  $\leq 1 \text{ h}^{-1}$ , sensitivity of the model  
40  
41 towards  $k_{\text{inact}}$  was decreased, and a further reduction of  $k_{\text{inact}}$  had no substantial impact on  
42  
43 the predicted exposure of unboosted LPV under steady state conditions. Therefore, we used a  
44  
45  $k_{\text{inact}}$  value of  $1 \text{ h}^{-1}$  for all further simulations. Since LPV is always administered with RTV, and  
46  
47 RTV is a much stronger mechanism-based inhibitor compared to LPV ( $k_{\text{inact}_{\text{RTV}}} = 19.8 \text{ h}^{-1}$ ,  
48  
49  $k_{\text{inact}_{\text{LPV}}} = 6 \text{ h}^{-1}$ <sup>12</sup>), it is highly likely that the DDI potential of the LPV/RTV combination is  
50  
51 attributed to the characteristics of RTV rather than LPV.  
52  
53  
54  
55  
56  
57  
58  
59
