

1 **Supplementary Materials/Methods**

2 **SNVPhyl Parameters**

3 Unless otherwise specified, SNVPhyl analyses for this study were run using the SNVPhyl workflow
4 version 1.0, with paired-end sequence reads, and with parameters:

- 5 • Variant quality parameters
 - 6 ○ Minimum coverage = 10X
 - 7 ○ Relative SNV abundance = 0.75
 - 8 ○ Minimum mean mapping quality = 30
- 9 • SNV density filtering
 - 10 ○ Window size = 20
 - 11 ○ SNV threshold = 2
- 12 • Repeat identification
 - 13 ○ Minimum length = 150
 - 14 ○ Minimum percent identity = 90%

15 All other parameters were left at the default settings as recorded in the SNVPhyl Galaxy workflow.

16 **Supplementary Figures and Tables**

17 Figure S1 was constructed using the phylogenetic trees produced in the “SNV density filtering
18 evaluation” section of the main manuscript. The tree produced from the “truth” set of SNVs
19 identified using Gubbins is used as a reference tree and is annotated as “Original alignment” in the
20 figure. This reference tree is compared to all other phylogenetic trees from each SNV-density
21 filtering scenario. The comparisons were made using the phytools [34] package in R.

22 Figure S2 was constructed using the phylogenetic trees produced in the “Parameter optimization”
23 section of the manuscript. The phylogenetic trees were evaluated for concordance with the
24 epidemiological data according to the conditions: 1) all outbreak isolates group monophyletically,
25 and 2) the maximum SNV distance between any two isolates within an outbreak clade must be less
26 than 5 SNVs. These conditions were tested and the figure constructed using the APE [37] package
27 within R.

28 Table S1 was constructed from previously published strain and accession identifiers [32]. These
29 were mapped to sequencing run accession identifiers using SRAdB [35].

30 Table S2 was constructed using information obtained from a previous study [36] along with
31 information from the project SRP067504 under the NCBI Sequence Read Archive.

32 Table S3 was constructed using the SNVs identified by SNVPhyl from the simulated dataset. The copy
33 numbers covering each position were determined by aligning each variant genome to the reference

34 genome using the MUMmer [25] software package. In particular, the command “show-snps” was
35 used to extract the number of alignments, and so copies, covering each position.
