#### Funding

The Sanu Gundo survey was sponsored and funded by the French National Agency for Research on Aids and Viral Hepatitis (ANRS) grant ANRS-12339 Sanu Gundo.

#### Abstract

**Objectives:** The aim of this article was to estimate HIV prevalence and the factors associated with HIV seropositivity using data from the Sanu Gundo cross-sectional survey conducted at the informal artisanal small-scale gold mining (IASGM) site of Kokoyo in Mali. Our main hypothesis was that HIV prevalence is higher in the context of IASGM than in the whole country.

**Settings:** The ANRS-12339 Sanu Gundo survey was conducted in December 2015 at Kokoyo, one of the largest IASGM sites in Mali with a population oscillating between 6 000 and 10 000 people. the Malian NGO ARCAD-SIDA, organized prevention activities, proposed rapid tests for HIV and invited people to take part in the survey. HIV prevalence was calculated for the sample, and for the different groups according to the type of activity in IASGM. A Probit logistic regression was implemented to estimate the characteristics associated with HIV seropositivity.

**Participants:** 224 respondents: 37.5% were gold-diggers, 33% retail traders, 6.7% *tombolomas* (i.e. traditional guards), 9% female sex-workers, while 14% reported another activity (mainly street vendors).

**Primary and secondary outcome measures:** HIV prevalence and HIV prevalence according groups defined by their activity in the Kokoyo IASGM.

#### **BMJ Open**

**Results:** HIV prevalence was 8% 98%CI[7.7%-8.3%], which is much higher than the 2015 national prevalence of 1.3% (UNAIDS). Probability of HIV seropositivity was 7.8% (p=0.037) higher for female non sex-workers than for any other category, and this probability increased significantly with age.

**Conclusions**: Our results demonstrate the importance of focusing on different categories of workers and the necessity to conduct further similar research on other Malian IASGM sites, in order to account for structural and geographical heterogeneity. Integrated policy-making should pay special attention to infectious diseases among populations in IASGM zones. Bringing information/prevention activities closer to people working in gold-bearing zones is an urgent public health action.

#### Strengths and limitations of this study

- This is the first study conducted in an informal and artisanal small-scale gold mining site in Mali involving all people directly or indirectly involved in informal mining activities.
- This study was conducted under the community-based framework, the survey design and research questions were elaborated with representatives of the informal mine of Kokoyo.
- The highest prevalence was found among female not sex-workers (13%) pointing out the importance of focusing on other less studied populations.
- There was an important proportion of participants in the survey that had never had a HIV test highlighting the importance of "proximity health services"
- The cross-sectional design of the Sanu Gundo survey did not enable us to analyse changes over time concerning different aspects, such as living and working conditions, seasonal mobility, and sexual behaviour

#### Introduction

The poverty-driven activities and demographic conditions in the world's informal artisanal small-scale gold mining (IASGM) sector contribute to its vulnerability to infectious diseases including HIV. This disease is recognized as one of the main public health issues in this sector, and potentially concerns close to 15 million people involved in IASGM activities across 70 countries <sup>1</sup>. Despite the high-risk of transmission <sup>2,3</sup>, and sustaining the spread of the disease <sup>4,5</sup>, very little is known about HIV epidemics in IASGM sites. Existing HIV literature on people working and living in gold mining sites mainly focuses on behavioural aspects, such as prevention <sup>6</sup>, attitudes towards voluntary counselling and testing <sup>7,8</sup>, the link between alcohol consumption and HIV <sup>9</sup>, and the role of gender in the response to HIV <sup>3,10,11</sup>. Furthermore, most studies have either been conducted among workers in industrial gold mines or in mining communities near gold-bearing zones which are not exclusively related to the IASGM sector. This is also the case for the few studies examining HIV prevalence: in South Africa in

the last decade was approximately 25% <sup>3,12,13</sup>, 22.3% for a group of Mozambican gold miners in 2012, and 4.5% and 6.4% for Guinea in 2001 and 2007, respectively <sup>14</sup>. We found only one study concerning an IAGSM site, in the Amazon region of Guyana, where HIV prevalence was 6.5% <sup>15</sup>. In addition, these studies principally focus on gold miners themselves and/or other presupposed at risk groups (e.g. female sex-workers), with little attention given to other categories of potentially high-risk people such as gold diggers (i.e. miners working in the informal sector), street vendors, and women who are not sex-workers, playing an important role in transmission and/or mobility of HIV. Indeed, focusing only on gold miners may divert the attention from these other high-risk groups <sup>2</sup>, as demonstrated by Clift *et al.* <sup>16</sup> in a community near two industrial gold-mines in Tanzania, where HIV prevalence was lower in mine workers (6%) than in men and women living at the mines but not directly involved in mining (respectively, 16% and 18%).

Gold mining is one of the cornerstones of the Malian economy, representing almost 70% of the country's total exports and 8% of the GDP in 2013<sup>17–19</sup>. Between 200 000 and 400 000 persons are estimated to be directly concerned by IASGM activities <sup>20,21</sup>. Despite the economic importance of the sector, little attention has been paid to health, demonstrated by the poor medical services provided in these sites <sup>22,23</sup> and the increasing demand for health, especially concerning HIV. The high prevalence observed in some key-populations provides a picture of the situation people may face in these sites. A demographic and health survey (EDSMV) conducted in Mali in 2012 showed that HIV prevalence among female sex-workers (24.2%), female street vendors (3.7%), and truckers (2.7%) was clearly higher than the national prevalence of approximately 1.2% in the same year. A few reports on IASGM in Mali have highlighted the urgent need to include the health dimension in economic-based research programs, especially concerning HIV. Community activities must be integrated into these programs as a tool to obtaining a greater understanding of the heterogeneity of IASGM, the functioning of this informal labour market <sup>2,24</sup>, and the impact of IASGM sector on the transmission and spread of infectious diseases.

In this context, we conducted the ANRS-12339 Sanu Gundo survey of the IASGM site at Kokoyo in Mali's Koulikoro region in December 2015, using a community-based research approach. The objective of this article was to estimate HIV prevalence - using the Sanu Gundo survey - for different groups present at Kokoyo, and the factors associated with HIV seropositivity.

#### Methods

#### The survey and population

The ANRS-12339 Sanu Gundo survey was conducted in December 2015 at Kokoyo (during 2 weeks), one of the largest IASGM sites in Mali with a population oscillating between 6 000 and 10 000

#### **BMJ Open**

people, depending on the season (rainy/dry). In collaboration with the Chamber of Mines and the Mines Ministry, this site was chosen given its geographical location implying a great deal of heterogeneity as people not only come from other Malian regions, but also from other neighbouring countries (Burkina Faso, Guinea, Nigeria, and Niger).

The study started with conversations about global health topics with a focus on HIV/STI prevention conducted by ARCAD-SIDA. Participants in the conversations were informed about the community-based services provided by the mobile ARCAD-SIDA unit including the provision of a medical check-up and essential medicines including those for treating STI. Furthermore, ARCAD-SIDA proposed rapid tests for HIV and invited people to take part in the survey. Eligibility criteria included: 1) aged at least 18 years; 2) able to speak French, Bambara, or English; and 3) able to provide written consent. Persons under the effects of alcohol and/or drugs were excluded. The convenience sample is formed by 224 participants that were randomly included in the study.

The *quantitative survey* consisted in a brief face-to-face questionnaire administered by trained investigators who collected information about the following: 1) sociodemographic/socioeconomic characteristics; 2) type of activity and mobility between sites; 3) HIV awareness, assessed with the following questions: have you heard about HIV? Have you ever been tested for HIV before today? Do you know your HIV status?; and 4) risky behaviours: alcohol and drugs consumption, sexual self-definition, type(s) and frequency of intercourse. The *qualitative survey* organized the participants into 5 activity-specific focus groups with semi-structured discussions about prevention and access to care for HIV/STI: Malian gold-diggers, Non-Malian gold-diggers, female sex-workers, female non sexworkers, and people guaranteeing the organizational functioning at the gold mine site (*damantiguis* and *tombolomas*). All procedures and documents used were validated by both French (CCTIRS N°15.917) and Malian (N°2015/65/CE/FMPOS) ethics committees.

#### Statistical analyses

The sample was described and HIV prevalence calculated for the overall sample, and for the different groups according to the type of activity in the gold mining site. A Probit logistic regression was implemented to estimate the characteristics associated with the probability of HIV seropositivity. All statistical analyses were conducted using R software <sup>25</sup>.

#### Results

#### Sample characteristics

The quantitative survey was conducted on convenience sample of 224 participants interested in prevention and medical activities provides by ARCAD-SIDA (Table 1): 101 women (45.1%) and 123

men (54.9%). There was a significant difference in average age between both genders: 25 and 29 years old (p<0.001), respectively. With respect to participants' main residence, 133 (59.4%) declared they lived in Mali: 28.5% in Kokoyo (i.e. autochthonous) and 71.5% from different cities (i.e. nonautochthonous) including Danga (the nearest) and Timbuktu (the farthest). The remaining 91 participants (40.6%) declared another country as their principal place of residence. Concerning marital status, 158 participants (70.5% of participants) declared they were married or lived in a couple. Among them, 50.6% lived with their spouse in Kokoyo and the remaining 49.4% were geographically single. Indeed, 72.1% of the 86 married/in a couple males who did not live with their spouse in Kokoyo declared living with another partner at the site, whereas the proportion of geographically single women was only 22.2% among the sample's 72 married/in a couple females, and none of them declared having another partner at the site. Socio-economic difficulties were observed in terms of education level, with 49.1% of the 224 participants reporting they had never been to school. Among the others, 27.7% and 9.8% had, respectively, a primary and secondary school educational level, 12.1% had a Koranic educational background, and 1.3% declared having postsecondary school education. With respect to their activity in Kokoyo, among the 224 respondents 37.5% were gold-diggers, 33% retail traders, 6.7% tombolomas, 9% female sex-workers, while 14% reported another activity (mainly street vendors). Approximately half of the sample comprised people living under the poverty threshold of 1.9 US\$ per day: 49.3% compared with 49.1% in the general Malian population (2009)<sup>26</sup>. Finally, 11.6% reported mobility between IASGM sites, and declared that Kokoyo was not the first IASGM site where they worked.

#### Table 1. Sample characteristics (n=224)

		n (%)
Gender		
	Male	123 (54.9)
	Female	101 (45.1)
Age: mean(sd)		27.5 (8.3)

Other activities (mainly street vendors)	31 (13.8)
Under the poverty threshold (1.9 US\$ per day)	
Yes	110 (49.1)
No	114 (50.9)
Have worked in other IASGM before Kokoyo	
Yes	26 (11.6)
No	198 (88.4)

#### HIV prevalence and new diagnoses

Seventeen new HIV-positive cases were found with the ARCAD-SIDA testing, among those tested at the time of the survey, and 1 HIV-positive case was self-reported. Overall, HIV prevalence was 8%, which is much higher than the 2015 national prevalence of 1.3% (UNAIDS) <sup>27</sup>. HIV prevalence was higher in women than in men, respectively, 10.4 and 5.9%. In terms of the 5 different categories studied, the highest HIV prevalence was in women who were not sex-workers (13%). Although lower than in women not sex-workers, prevalence in female sex-workers was higher (3.7%) at the Kokoyo site than the national prevalence for sex-workers. Prevalence in both non-Malian and Malian male gold-diggers was high, respectively, 7.7% and 6.5% whereas prevalence in males other than gold diggers was 6.4%. No HIV-positive case was observed in traditional guards.

The quantitative survey showed that 63.4% participants (142 out of 224) had never had a HIV test. Of these, 7 (4.9%) - 5 women and 2 men - tested positive for HIV using ARCAD-SIDA's test. This corresponded to 38.9% of the total 18 (11 women and 7 men) HIV seropositive participants observed, (or 45.5% (5/11) of total HIV women and 28.6% (2/7) of total HIV men). Among the 5 HIV positive cases for women 1 was a sand washer, 1 was female sex-worker and 3 were street vendors.

Among the 2 HIV positive cases for men 1 was a non-Malian gold digger and 1 was a male street vendor.

#### Factors associated to HIV seropositivity

Multivariate probit regression was implemented to estimate the factors associated with HIV seropositivity among the 224 participants in the quantitative survey (Table 2). Estimates show that the probability of HIV seropositivity was 7.8% (p=0.037) higher for female non sex-workers than for any other category, and this probability increased significantly with age. Indeed, the probability of HIV seropositivity - with respect to the youngest participants (aged between 18 and 21 years) – was 14.1% (p=0.034), 14.2% (p=0.036) and 16.1% (p=0.021) higher for participants aged 22-26 years, 27-29 years, and 30+ years, respectively. Finally, a 10.9% lower probability of HIV seropositivity was observed in participants who perceived their health status as good (versus poor).

#### Table 2. Factors associated with HIV seropositivity (n=224)

1 Is the change in the probability given the change in each independent continuous variable and reports the discrete change in the probability for dichotomous variables.

**2** Age categories' cut-offs correspond to quartiles.

3 The median weekly earning is 14 500 FCFA (25 US\$). This variable was used to account for the socioeconomic status of participants.

#### Main findings of the qualitative survey

Five focus groups were carried out over 28 participants according to gender and professional status: 6 *tombolomas*, 6 Malian male gold diggers, 5 non-Malian male gold diggers, 5 women sex-workers and 6 women non sex-workers. The first discourse identified refers to sexual practices, especially non-systematic condom use, women sex-workers charging extra for condomless sexual intercourse, and the undisclosed use of female condoms. Participants attributed these practices to the following factors: the place where sexual intercourse took place: bars *versus* the street; the nationality/ethnicity of female sex-workers: Malians and Guineans were seen as more "flexible" than Nigerians (considered as "strict") with regards to condom use; and the nature of the relationship between men and women: trustful relationships (considered "safer") than strictly commercial-sex relationships (considered "risky"). The second discourse identified referred to health services access, with the main barrier being the long distances. Other barriers evoked were the high price of medicines, the lack of specialists and other health care providers, as well as the poor number and quality of HIV/STI information/prevention programmes described as the main reasons why participants resorted to traditional medicine.

#### Discussion

This is the first study conducted in an informal and artisanal small-scale gold mining site in Mali which investigates HIV not only in those directly involved in informal mining (i.e. gold diggers), but also in other populations with a related activity at the site. The aims of the present article emerged from the need for the authorities of the IASGM site at Kokoyo to characterize the population living there, and to provide community-based prevention and HIV testing as part of the health care services offered.

The low education level observed and the high proportion of participants living with revenues below the 1.9 US\$ poverty-line threshold, confirmed the poverty-driven characteristic of IASGM sites reported in the literature concerning other countries with large gold-bearing zones <sup>22,28</sup>. The fluctuation of the population suggests large-scale cyclical migration of workers (i.e. they stay for a period, go back home, and the next season they return either to the same or to another mine), and as Rees et al. suggested, they are often separated from their family (i.e. geographically single) <sup>12</sup>. This is confirmed by our results where 71.5% of Malian participants came from other regions of Mali (non-autochthonous), and 40.6% of the total sample were not Malian. Moreover, geographically single individuals accounted for 49.4% of the 158 participants who reported being married or living in

a couple. This "bridge population" cohabits with other high-risk groups in the IASGM site at Kokoyo representing potential source for the sustained spread of infectious diseases - including HIV - at the site, and at their home <sup>4,5</sup>. Indeed, being single (geographically or not) is associated with risky behaviours, given the freedom from social norms and the economic difficulties that prevail in IASGM sites <sup>2</sup>. Furthermore, working conditions and the inherent related dangers which male gold diggers are confronted with, have also been identified as factors related to an increase in risky behaviours <sup>3,30</sup>.

This is the first time that HIV prevalence has been estimated in an IASGM site in Mali. We found a HIV prevalence of 8% in the 224 participants in our study, which is much higher than the Malian national prevalence of 1.3% estimated in 2015, this is in line with the 7% estimated for the IASGM site of Tenkoto in the Kédougou region of Senegal <sup>31</sup>. In addition, HIV prevalence varied for the different categories studied, ranging between 3.6% for female sex-workers to 13% for both women gold diggers and women street vendors. The latter value is in line with the 13% estimated for street vendors in Burkina Faso, although that value was not specific to IASGM sites <sup>32</sup>. Our estimates not only reflect the results from the few qualitative studies performed to date which suggest high prevalence of HIV in IASGM sites, but also highlight that accounting for other categories of people than simply those directly involved in mining, other "less classic" groups are seen to be at higher risk <sup>2</sup>.

The acceptability of HIV testing by participants observed in this study demonstrated not only that the community-based dimension is crucial to conduct this kind of research <sup>2,7</sup>, but that it is also useful for the provision of prevention and HIV testing to this population. This is one of the main contributions of our analysis, and highlights the large demand-supply gap for health care services in Kokoyo. Indeed, the nearest Rural Health Community Centre (CSCOM, Centre de Santé Communautaire) does not provide either prevention or testing for HIV, and the only two centres of voluntary testing in the Koulikoro region are far from gold-bearing zones, especially the IASGM site of Kokoyo. This community-based research identified a large number of new HIV positive cases, and this is another important contribution of the study. Most specifically, 38% among the 18 HIV positive participants in the quantitative survey corresponded to new diagnoses using ARCAD-SIDA's rapid tests. Women were mostly concerned (5 out of 11 positive cases in women were new diagnoses), especially street vendors. Although ARCAD-SIDA referred all 18 HIV positive participants to the nearest regional hospitals (CSREF) in order to link them to care, the emerging question is whether or not these participants subsequently initiated and adhered to antiretroviral treatment given the distance of more than 100km between Kokoyo and Kangaba city where the CSREF is located. Unfortunately, we have no information about lost-to-follow-up rates in people living with HIV in the context of IASGM

#### **BMJ Open**

sites, but presumably these rates are high given that HIV is not of primary concern to people in IASGM sites, as suggested by Campbell <sup>3</sup>. This certainly seems to be the situation in Kokoyo, where the large majority of study participants aware of HIV (over 90%) had never previously gone for a test (63.4%). Multivariate analyses pointed out female non sex-workers, the eldest participants, and those with poor self-perceived health status as the three sub-populations most associated with HIV seropositivity.

Some limitations should be acknowledged. First, the study sample is not representative of the whole population in IASGM sites in Mali. However, our results seemed to reflect those in the literature. Second, the cross-sectional design of the Sanu Gundo survey did not enable us to analyse changes over time concerning different aspects, such as living and working conditions, seasonal mobility, and sexual behaviour. Furthermore, although the participants who tested positive for HIV during the study were referred to the regional hospital, the design of the survey did not allow us collect subsequent information, either concerning linkage-to-care or antiretroviral treatment initiation. Finally, there is a possibility of selection bias, as the sample was drawn from the healthcare conversation audience organized by ARCAD-SIDA. This selection bias would reflect an audience mainly comprising individuals interested in prevention and to some extent, worried by health issues, especially HIV. One would expect that any future study whose design were to attract participants other than those already interested in health care, would result in higher HIV prevalence being measured and would accentuate the precarious characteristics already described by our survey at Kokoyo. Despite these limitations, our study contributes to the existing literature by creating a knowledge base which could be a useful first step for the development of suitable surveys and interventions.

#### Conclusion

The results of this study demonstrate the importance of focusing on different categories of workers and the necessity to conduct further similar research on other Malian IASGM sites, in order to account for structural and geographical heterogeneity. The present article contributes to the literature by reopening the debate about the impact of Health issues on IASGM activities, especially HIV issues, in a context where the sustained spread of this disease could not only harm efforts in the fight against AIDS, but also have important negative consequences in one of the main cornerstones of the Malian economy. Integrated policy-making should pay special attention to infectious diseases among populations in IASGM zones. Bringing information/prevention activities closer to people working in gold-bearing zones is an urgent public health action.

### Authors contribution

LST designed and led the study and wrote the first draft of the report. LST, MSM, BS and BDK designed the analysis. LST, HB and FD analysed the data. MM and MB oversaw data management. All authors critically reviewed and approved the manuscript.

## STROBE 2007 (v4) Statement—Checklist of items that should be included in reports of cross-sectional studies

Section/Topic	ltem #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	2-3
Objectives	3	State specific objectives, including any prespecified hypotheses	3
Methods			
Study design	4	Present key elements of study design early in the paper	4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	4
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	4
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	4
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	NA
Bias	9	Describe any efforts to address potential sources of bias	4
Study size	10	Explain how the study size was arrived at	4
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	4
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	4
		(b) Describe any methods used to examine subgroups and interactions	NA
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	NA
Results			

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

**BMJ Open** 

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility,	NA
		confirmed eligible, included in the study, completing follow-up, and analysed	
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	5
		(b) Indicate number of participants with missing data for each variable of interest	NA
Outcome data	15*	Report numbers of outcome events or summary measures	6
Main results	16	( <i>a</i> ) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	7
		(b) Report category boundaries when continuous variables were categorized	7
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	NA
Discussion			
Key results	18	Summarise key results with reference to study objectives	8
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	
Generalisability	21	Discuss the generalisability (external validity) of the study results	10
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on	
		which the present article is based	

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

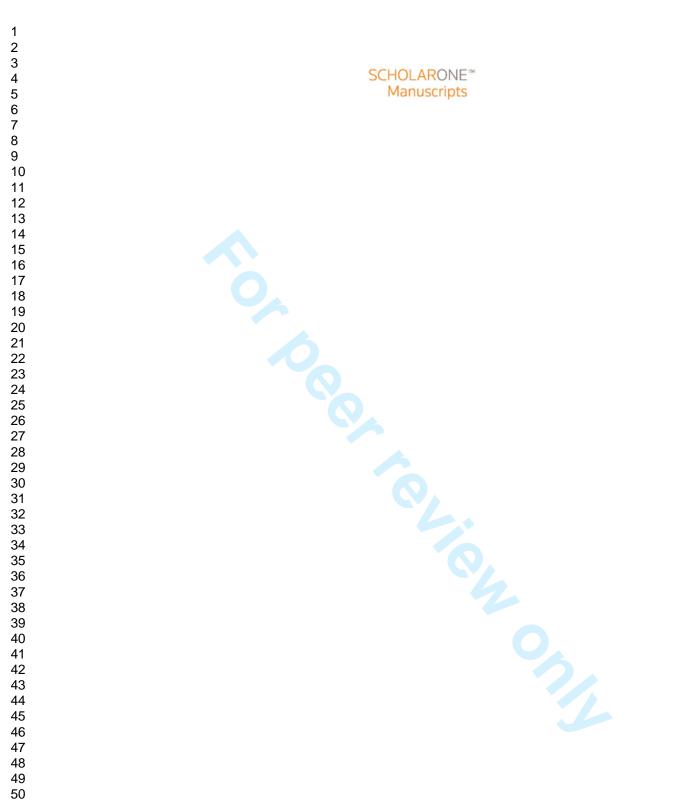

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). #### Funding

The Sanu Gundo survey was sponsored and funded by the French National Agency for Research on Aids and Viral Hepatitis (ANRS) grant ANRS-12339 Sanu Gundo.

## Abstract

**Objectives:** The aim of this article was to estimate HIV prevalence and the factors associated with HIV seropositivity in the population living and working at the informal artisanal small-scale gold mining (IASGM) site of Kokoyo in Mali, using data from the Sanu Gundo cross-sectional survey. Our main hypothesis was that HIV prevalence is higher in the context of IASGM than in the country as a whole.

**Settings:** The ANRS-12339 Sanu Gundo survey was conducted in December 2015 at Kokoyo, one of the largest IASGM sites in Mali (between 6 000 and 10 000 people). The quantitative survey consisted in face-to-face administration of questionnaires. Five focus groups were conducted for the qualitative survey. HIV prevalence was calculated for the sample, and for the different sub-groups within the sample, according to the type of activity performed in IASGM. A Probit logistic regression was implemented to estimate the characteristics associated with HIV seropositivity.

#### **BMJ Open**

**Participants:** 224 respondents: 37.5% were gold-diggers, 33% retail traders, 6.7% *tombolomas* (i.e. traditional guards), and 9% female sex-workers. The remaining 13.8% reported another activity (mainly street vending).

**Primary and secondary outcome measures:** HIV prevalence and HIV prevalence according to subgroup, as defined by their activity at the Kokoyo IASGM.

**Results:** HIV prevalence for the total sample was 8% 95%CI[7.7%-8.3%], which is much higher than the 2015 national prevalence of 1.3% (UNAIDS). The probability of HIV seropositivity was 7.8% (p=0.037) higher for female non sex-workers than for any other category, and this probability increased significantly with age. Qualitative data revealed the non-systematic use of condoms with sex-workers; and long distance from health services was the main barrier to accessing care.

**Conclusions**: Integrated policy-making should pay special attention to infectious diseases among populations in IASGM zones. Bringing information/prevention activities closer to people working in gold-mining zones is an urgent public health action.

#### Strengths and limitations of this study

- This is the first study conducted in an informal and artisanal small-scale gold mining site in Mali including all of the people directly or indirectly involved in the site's activities.
- This study was implemented using a community-based research approach, the survey design and research questions being developed in collaboration with representatives of the mine of Kokoyo.
- The highest HIV prevalence was found among female non sex-workers (13%), which highlights the importance of focusing on high-risk less-studied populations.
- A large proportion of participants in the survey had never had a HIV test, which highlights the importance of "close proximity health services"
- The cross-sectional design of the Sanu Gundo survey did not enable us to analyse changes over time concerning several socio-economic and behavioural aspects, such as living and working conditions, seasonal mobility, or sexual behaviour

#### Introduction

The poverty-driven activities and demographic conditions in the world's informal artisanal small-scale gold mining (IASGM) sector contribute to its vulnerability to infectious diseases including HIV. This disease is recognized as one of the main public health issues in this sector, and potentially concerns almost 15 million people involved in IASGM activities across 70 countries <sup>1</sup>. Despite the high risk of transmission <sup>2,3</sup>, and sustained spread of the disease <sup>4,5</sup>, very little is known about HIV epidemics in

IASGM sites. Existing HIV literature on people working and living in gold mining sites mainly focuses on behavioural aspects, such as prevention <sup>6</sup>, attitudes towards voluntary counselling and testing <sup>7,8</sup>, the link between alcohol consumption and HIV<sup>9</sup>, and the role of gender in the fight against HIV<sup>3,10,11</sup>. Furthermore, most studies have either been conducted among workers in industrial gold mines or in mining communities near gold-bearing zones which are not exclusively related to the IASGM sector. This is also the case of the few studies examining HIV prevalence, which in South Africa in the last decade was measured at approximately 25% <sup>3,12,13</sup>, at 22.3% for a group of Mozambican gold miners in 2012, and at 4.5% and 6.4% for Guinea in 2001 and 2007, respectively <sup>14</sup>. We found only one study concerning an IASGM site, specifically in the Amazon region of Guyana. HIV prevalence there was 6.5% <sup>15</sup>. In addition, these studies principally focus on gold miners themselves and/or other presupposed most-at-risk groups (e.g. female sex-workers), with little attention given to other categories of potentially high-risk people such as gold diggers (i.e. miners working in the informal sector), women who are not sex-workers, and street vendors, all of whom play an important role in the transmission and/or mobility of HIV. Indeed, focusing only on gold miners and not including these other high-risk groups may be detrimental to the fight against HIV<sup>2</sup>, as demonstrated by Clift et al.<sup>16</sup> in a community near two industrial gold-mines in Tanzania, where HIV prevalence was lower in mine workers (6%) than in men and women living at the mines but not directly involved in mining (respectively, 16% and 18%).

Gold mining is one of the cornerstones of the Malian economy, representing almost 70% of the country's total exports and 8% of the GDP in 2013<sup>17–19</sup>. Between 200 000 and 400 000 persons are estimated to be directly concerned by IASGM activities <sup>20,21</sup>. Despite the economic importance of the sector, little attention has been paid to health, as demonstrated by both the poor medical services provided in these sites <sup>22,23</sup> and the increasing demand for health, especially concerning HIV. The high prevalence observed in some key populations provides a picture of the situation people may face in these sites. A demographic and health survey (EDSMV) conducted in Mali in 2012 showed that HIV prevalence among female sex-workers (24.2%), female street vendors (3.7%), and truckers (2.7%) was much higher than the national prevalence of approximately 1.2% in the same year. Different reports on IASGM in Mali have highlighted the urgent need to include the health dimension in economic-based research programs, especially concerning HIV. Community-based activities (e.g., prevention, screening, counselling etc.) could help do this as they could help provide a greater understanding of the heterogeneity of IASGM, the functioning of this informal labour market <sup>2,24</sup>, and the impact of IASGM sector on the transmission and spread of infectious diseases.

We conducted the ANRS-12339 Sanu Gundo survey of the IASGM site at Kokoyo in Mali's Koulikoro region in December 2015, using a community-based research approach. The objective of this article

#### **BMJ Open**

was to estimate HIV prevalence - using the Sanu Gundo survey – in different groups present at Kokoyo, and the factors associated with HIV seropositivity.

#### Methods

#### Settings and design

The ANRS-12339 Sanu Gundo survey was conducted in December 2015 at Kokoyo (for 2 weeks), one of the largest IASGM sites in Mali with a population oscillating between 6 000 and 10 000 people, depending on the season (rainy/dry). In collaboration with the Chamber of Mines and the Mines Ministry, this site was chosen for its geographical location because of the great deal of cultural heterogeneity there. People come not only from other Malian regions, but also from neighbouring countries (Burkina Faso, Guinea, Nigeria, and Niger).

The study started with conversations about global health topics with a focus on HIV/STI prevention which were facilitated by ARCAD-SIDA members. Participants in the conversations were informed about the community-based services provided by the mobile ARCAD-SIDA unit, including the provision of a medical check-up and essential medicines including those for treating STI. Furthermore, ARCAD-SIDA proposed rapid tests for HIV and invited people to take part in the survey. For HIV screening, ARCAD-SIDA follows the Malian Ministry of Health recommendations using Determine® rapid tests, and ImmunoComb® II for confirmation. ARCAD-SIDA provided counselling about the importance of being treated to participants testing HIV positive, and referred them to regional health care centres (Centre de Santé de Référence, CSREF) for blood assessment and inclusion in treatment and follow-up programmes.

Participants in the conversations were then invited to participate in the qualitative and quantitative surveys (they could choose either or both) which formed the basis for the ANRS-12339 Sanu Gundo survey. Community-based agents sent those interested to the Malian team of researchers, who in turn provided detailed information about the content of the survey, its main objectives, and the advantages/risks of participating in this kind of survey. Survey participants provided written formal consent to participate in the survey(s) by signing a letter of consent. All procedures and documents used were validated by both French (CCTIRS N°15.917) and Malian (N°2015/65/CE/FMPOS) ethics committees.

#### **Participants**

Eligibility criteria included: i) aged 18 years or older; ii) able to speak French, Bambara, or English; iii) able to provide written consent to participate. Persons under the effects of alcohol and/or drugs were excluded. For the *quantitative survey*, 224 participants constituted the convenience sample. In order to reduce any potential over-representation and under-representation sampling bias, ARCAD-SIDA activities were conducted every day at different time slots and locations at the site in order to adapt participant recruitment to the work schedule of the different categories of people living there. To those who agreed to participate in the survey(s), a brief face-to-face questionnaire was administered by trained investigators who collected information about the following : i) sociodemographic and socioeconomic characteristics: age (continuous variable), gender, marital status, country of residence, educational level, and weekly earnings (dichotomized at the median of 14 500 FCFA, approximately 24.26 US\$ ) ; ii) type of activity and mobility between sites; iii) HIV awareness, assessed with the following questions: "Have you heard about HIV?" "Have you ever been tested for HIV before today?", "Do you know your HIV status?"; iv) risky behaviours: alcohol and drugs consumption, sexual self-definition, type(s) and frequency of intercourse; v) perceived health status, assessed with the following question: "How do you consider your state of health today?", with possible answers including "very poor", "poor", "moderate", "good", and "very good". This variable was equal to 1 for those perceiving their health was good or very good, and 0 for those perceiving they had poor or very poor health. For the qualitative survey, purposive sampling was implemented. This seemed to be the most suitable sampling method as the main objective of the qualitative survey was to collect information about prevention and access to care for HIV/STI among specific groups. The sample size for each group was fixed between 5 and 8 survey participants in order to ensure diversity among them. Five activity-specific focus groups were organized: Malian gold-diggers, Non-Malian gold-diggers, female sex-workers, female non sex-workers, and people guaranteeing the organizational functioning at the gold mine site (*damantiquis* and *tombolomas*).

#### Statistical analyses

The sample was described and HIV prevalence calculated both for the overall sample, and for the different sub-groups listed above (i.e., according to the type of activity in the gold mining site). A Probit logistic regression was implemented to estimate the characteristics associated with the probability of HIV seropositivity. Given the nature of the normal distribution assumption of the error term in the Probit estimation, coefficients are not affected by the presence of extreme values in independent variables. Furthermore, Probit regression allows the computation of marginal effects that are more flexible and more informative than odd-ratios <sup>25,26</sup> which tend to be larger in the

#### **BMJ Open**

presence of rare events and are in any case preferred for small samples<sup>27</sup>. Marginal effects, dF/dX, are interpreted as instantaneous rates of change: for a dichotomous explanatory variable, a marginal effect shows how predicted probabilities change when the variable changes from 0 to 1. All statistical analyses were performed using R software <sup>28</sup>.

#### Results

#### Sample characteristics

The quantitative survey was conducted on a convenience sample of 224 participants interested in prevention and medical activities provided by ARCAD-SIDA (Table 1): 101 women (45.1%) and 123 men (54.9%). There was a significant difference in average age between both genders: 25 and 29 years old respectively. With respect to participants' main residence, 133 (59.4%) declared they lived in Mali: 28.5% in Kokoyo (i.e. autochthonous) and 71.5% from different cities (i.e. nonautochthonous) including Danga (the nearest) and Timbuktu (the farthest). The remaining 91 participants (40.6%) declared another country as their principal place of residence. With respect to marital status, 158 participants (70.5% of the whole sample) declared they were married or lived in a couple. Among them, 50.6% lived with their spouse in Kokoyo and the remaining 49.4% were geographically single. Of the 86 married/in a couple males who did not live with their spouse in Kokoyo 72.1% declared living with another partner at the site. Conversely, the proportion of geographically single women was only 22.2% among the sample's 72 married/in-a-couple females, and none declared having another partner at the site. Socio-economic difficulties were observed in terms of educational level, with 49.1% of the 224 participants reporting they had never been to school. Among the others, 27.7% and 9.8% had, respectively, a primary and secondary school educational level, 12.1% had a Koranic educational background, and 1.3% declared having postsecondary school education. With respect to their activity in Kokoyo, among the 224 respondents 37.5% were gold-diggers, 33% retail traders, 6.7% tombolomas, 9% female sex-workers, while 14% reported another activity (mainly street vending). Approximately half of the sample comprised people living under the poverty threshold of 1.9 US\$ per day: 49.3% compared with 49.1% in the general Malian population (2009) <sup>29</sup>. Finally, 11.6% reported mobility between IASGM sites, and declared that Kokoyo was not the first IASGM site where they had worked.

## Table 1. Sample characteristics of participants living in the informal artisanal small-scale gold mining site (IASGM) of Kokoyo in Mali (n=224)

#### HIV prevalence and new diagnoses

Seventeen new HIV-positive cases were found with the ARCAD-SIDA testing, among those tested at the time of the survey, and 1 HIV-positive case was self-reported. Overall, HIV prevalence was 8% 95%CI[4.5%, 11.6%],. HIV prevalence was higher in women than in men, respectively, 10.4 95%CI[4.5%, 16.2%] and 5.9% 95%CI[1.7%, 6.5%]. In terms of the 5 different categories studied, the highest HIV prevalence was in women who were not sex-workers (13% 95%CI[5.4%, 20.3%]). Although lower than in the latter group, the prevalence in female sex-workers was still higher (3.7% 95%CI[-3.5%, 10.9%]) at the Kokoyo site than the national prevalence for sex-workers (irrespective of gender). Prevalence in both non-Malian and Malian male gold-diggers was high, respectively, 7.7% 95%CI[-7.4%, 22.8%] (90%CI[-4.9%, 20.4%]) and 6.5% 95%CI[-0.7%, 13.7%] (90%CI[0.5%, 12.6%]), whereas prevalence in males other than gold diggers was 6.4% 95%CI[-0.7%, 13.5%] (90%CI[0.5%, 12.3%]). No HIV-positive case was observed in traditional guards (*tombolomas*).

The quantitative survey showed that 63.4% participants (142 out of 224) had never had a HIV test. Of these, 7 (4.9%) - 5 women and 2 men - tested positive for HIV using ARCAD-SIDA's test. This corresponded to 38.9% of the total 18 (11 women and 7 men) HIV seropositive participants observed, (or 45.5% (5/11) of total HIV women and 28.6% (2/7) of total HIV men). Among the 5 HIV positive cases for women, 1 was a sand washer, 1 was a female sex-worker and 3 were street vendors. Among the 2 HIV positive cases for men, 1 was a non-Malian gold digger and 1 a male street vendor.

#### Factors associated to HIV seropositivity

A multivariate probit regression was implemented to estimate the factors associated with HIV seropositivity among the 224 participants in the quantitative survey (Table 2). Estimates show that the probability of HIV seropositivity was 7.8% (p=0.037) higher for female non sex-workers than for any other category, and this probability increased significantly with age. Indeed, the probability of HIV seropositivity - with respect to the youngest participants (aged between 18 and 21 years) – was 14.1% (p=0.034), 14.2% (p=0.036) and 16.1% (p=0.021) higher for participants aged 22-26 years, 27-29 years, and 30+ years, respectively. Finally, a 10.9% lower probability of HIV seropositivity was observed in participants who perceived their health status as good (versus poor).

 Table 2. Factors associated with HIV seropositivity among participants living in the informal artisanal small-scale gold mining site (IASGM) of Kokoyo in Mali (n=224)

1 Is the change in the probability given the discrete change for dichotomous variables.

**2** Age categories' cut-offs correspond to quartiles.

3 The median weekly earning is 14 500 FCFA (25 US\$). This variable was used to account for the socioeconomic status of participants.

#### Main findings of the qualitative survey

Five focus groups were carried out over 28 participants according to gender and professional status: 6 *tombolomas*, 6 Malian male gold diggers, 5 non-Malian male gold diggers, 5 female sex-workers and 6 women non sex-workers. Among the discourses identified, one referred to sexual practices, especially non-systematic condom use, women sex-workers charging extra for condomless sexual intercourse, and the undisclosed use of condoms by women. Participants attributed these practices to the following factors: i) the place where sexual intercourse took place: bars *versus* the street; ii) the nationality/ethnicity of female sex-workers: Malians and Guineans were seen as more "flexible" than Nigerians (considered as "strict") with regards to condom use; and iii) the nature of the relationship between men and women: trustful relationships (considered "safer") than strictly

#### **BMJ Open**

commercial-sex relationships (considered "risky"). Another discourse identified referred to health services access, with the main barrier being the long distances involved. Other barriers mentioned were the high price of medicines, the lack of specialists and other health care providers, as well as the low number and poor quality of HIV/STI information/prevention programmes described. These barriers were also the main reasons why participants resorted to traditional medicine.

#### Discussion

This is the first study conducted in an informal and artisanal small-scale gold mining site in Mali which investigates HIV not only in those directly involved in informal mining (i.e. gold diggers), but also in other populations with a related activity. The aims of this article were drawn up specifically to respond to the need for the authorities of the IASGM site at Kokoyo to characterize the population living there, and to provide community-based prevention and HIV testing as part of the health care services offered.

The low educational level observed and the high proportion of participants living with revenues below the 1.9 US\$ poverty-line threshold, reflects the high level of poverty reported in the literature concerning IASGM sites in other countries with large gold-bearing zones <sup>22,30</sup>. The fluctuation of the population at Kokoyo suggests large-scale cyclical migration of workers (i.e. they stay for a period, go back home, and the next season they return either to the same mine or to another). Rees et al. suggested they such workers are often separated from their family (i.e. geographically single) <sup>12</sup>, something confirmed by our results where 71.5% of Malian participants came from other regions of Mali (non-autochthonous), and 40.6% of the total sample were not Malian. Moreover, geographically single individuals accounted for 49.4% of the 158 participants who reported being married or living in a couple. This "bridge population" cohabits with other high-risk groups in the IASGM site at Kokoyo, representing a potential source for the continued spread of infectious diseases - including HIV - at the site, and at their home  $^{4,5}$ . Indeed, being single (geographically or not) is associated with risky behaviours, given the freedom from social norms and the economic difficulties that prevail in IASGM sites<sup>2</sup>. Furthermore, working conditions and the inherent related dangers which male gold diggers are confronted with, have also been identified as factors related to an increase in risky behaviours 3,31

This is the first time that HIV prevalence has been estimated in an IASGM site in Mali. We found a prevalence of 8% in the 224 participants in our study, which is much higher than the Malian national prevalence of 1.3% estimated in 2015<sup>32</sup>, but is in line with the 7% estimated for the IASGM site of Tenkoto in the Kédougou region of Senegal <sup>33</sup>. In addition, HIV prevalence varied for the different

categories studied, ranging between 3.6% for female sex-workers to 13% for both women gold diggers and women street vendors. The latter value is in line with the 13% estimated for street vendors in Burkina Faso, although that value was not specific to IASGM sites <sup>34</sup>. Our estimates not only reflect the results from the few qualitative studies performed to date which suggest high prevalence of HIV in IASGM sites, but also highlight that "less classic" groups (i.e. those not directly involved in mining) are at higher risk <sup>2</sup>. The different HIV prevalence rates found across groups may reflect the lack of prevention programs adapted to key populations other than sex-workers in Mali. Most of the efforts in the fight against HIV/AIDS in Mali are concentrated on female sex-workers and men having sex with other men (MSM), who are identified as the most vulnerable groups. This could explain - at least in part - the low prevalence rate among female sex-workers in Kokoyo IASGM and the higher prevalence among other groups, including female non-sex workers and gold-diggers. Indeed participants from these two categories expressed during the focus groups that prevention campaigns are mostly directed at female sex-workers, who seem to be more informed about the risk of HIV contamination and about prevention tools.

The acceptability of HIV testing by participants observed in this study demonstrated not only that the community-based dimension is crucial to conduct this kind of research <sup>2,7</sup>, but that it is also useful for the provision of prevention and HIV testing to this population. Of the 236 persons invited to test for HIV, only 5% refused. This is one of the main contributions of our analysis, and highlights the large demand-supply gap for health care services in Kokoyo. Indeed, the nearest Rural Health Community Centre (CSCOM, Centre de Santé Communautaire) does not provide either prevention or testing for HIV, and the only two centres of voluntary testing in the Koulikoro region are far from gold-bearing zones, especially the IASGM site of Kokoyo. This community-based research identified a large number of new HIV positive cases, and this is another important contribution of the study. More specifically, 38% of the 18 HIV-positive participants in the quantitative survey were newly diagnosed using ARCAD-SIDA's rapid tests. Five out of 11 positive cases in women were new diagnoses, especially female street vendors. Although ARCAD-SIDA referred all 18 HIV positive participants to the nearest regional hospitals (CSREF) in order to link them to care, the emerging question is whether or not these participants subsequently initiated and adhered to antiretroviral treatment given the distance of more than 100km between Kokoyo and Kangaba city where the CSREF is located. Unfortunately, we have no information about lost-to-follow-up rates in people living with HIV in the context of IASGM sites, but presumably these rates are high given that HIV is not of primary concern to people in IASGM sites, as suggested by Campbell<sup>3</sup>. This certainly seems to be the situation in Kokoyo, where the large majority of study participants aware of HIV (over 90%) had never previously gone for a test (63.4%). Multivariate analyses indicated that female non sex-workers, the eldest

#### **BMJ Open**

participants, and those with poor self-perceived health status were the three sub-populations most associated with HIV seropositivity.

Some limitations should be acknowledged. First, the study sample is not representative of the whole population in IASGM sites in Mali. However, our results reflect those in the literature. Second, the cross-sectional design of the Sanu Gundo survey did not enable us to analyse changes over time concerning different aspects, such as living and working conditions, seasonal mobility, and sexual behaviour. Furthermore, although the participants who tested positive for HIV during the study were referred to the regional hospital, the design of the survey did not allow us collect subsequent information, either concerning linkage-to-care or antiretroviral treatment initiation. Finally, there is a possibility of selection bias, as the sample was drawn from the healthcare conversation audience organized by ARCAD-SIDA. Nevertheless, any selection bias would reflect an audience mainly comprising individuals interested in prevention and to some extent, worried about health issues, especially HIV. One would expect that any future study whose design were to attract participants other than those already interested in health care, would result in higher HIV prevalence being measured and would accentuate the precarious characteristics already described by our survey at Kokoyo. Despite these limitations, our study contributes to the existing literature by creating a knowledge base which could be a useful first step for the development of suitable surveys and interventions.

#### Conclusion

The results of this study demonstrate the importance of focusing on different categories of workers and the necessity to conduct further similar research on other Malian IASGM sites, in order to account for structural and geographical heterogeneity. The present article contributes to the literature by reopening the debate about the impact of health issues on IASGM activities, especially HIV issues, in a context where the sustained spread of this disease could not only harm efforts in the fight against AIDS, but also have important negative consequences on one of the main cornerstones of the Malian economy. Integrated policy-making should pay special attention to infectious diseases among populations in IASGM zones. Bringing information/prevention activities closer to people working in gold-bearing zones is an urgent public health action.

#### Authors' contribution

LST designed and led the study and wrote the first draft of the report. LST, MSM, BS and BDK designed the analysis. LST, HB and FD analysed the data. MM and MB oversaw data management. All authors critically reviewed and approved the manuscript.

# STROBE 2007 (v4) Statement—Checklist of items that should be included in reports of cross-sectional studies

Section/Topic	ltem #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	2-3
Objectives	3	State specific objectives, including any prespecified hypotheses	3
Methods			
Study design	4	Present key elements of study design early in the paper	4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	4
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	4
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	4
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	NA
Bias	9	Describe any efforts to address potential sources of bias	4
Study size	10	Explain how the study size was arrived at	4
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	4
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	4
		(b) Describe any methods used to examine subgroups and interactions	NA
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	NA
Results			

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

**BMJ Open** 

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility,	NA
		confirmed eligible, included in the study, completing follow-up, and analysed	
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	5
		(b) Indicate number of participants with missing data for each variable of interest	NA
Outcome data	15*	Report numbers of outcome events or summary measures	6
Main results	16	( <i>a</i> ) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	7
		(b) Report category boundaries when continuous variables were categorized	7
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	NA
Discussion			
Key results	18	Summarise key results with reference to study objectives	8
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	10
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	10
Generalisability	21	Discuss the generalisability (external validity) of the study results	10
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on	
		which the present article is based	

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

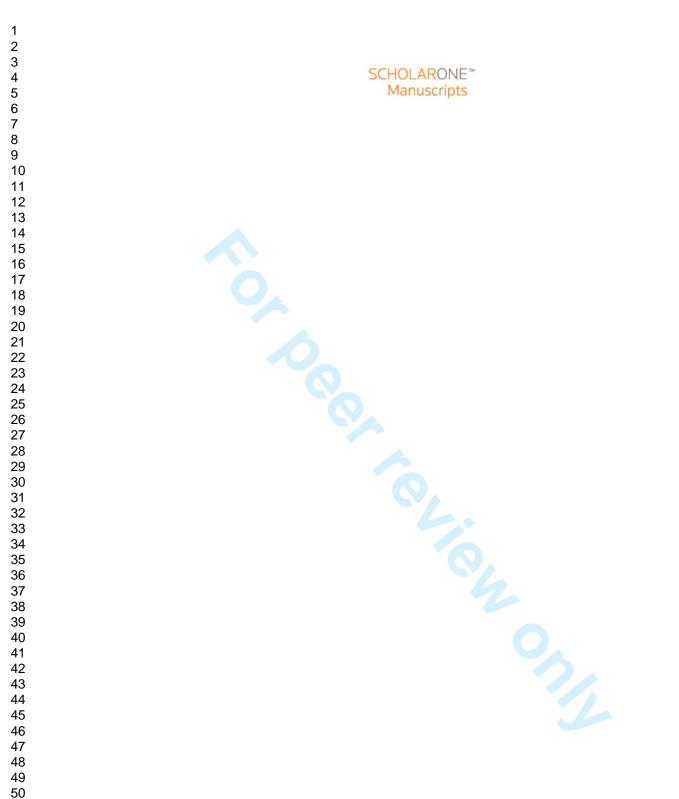

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). #### Funding

The Sanu Gundo survey was sponsored and funded by the French National Agency for Research on Aids and

Viral Hepatitis (ANRS) grant ANRS-12339 Sanu Gundo.

## Abstract

**Objectives:** The aim of this article was to estimate HIV prevalence and the factors associated with HIV seropositivity in the population living and working at the informal artisanal small-scale gold mining (IASGM) site of Kokoyo in Mali, using data from the Sanu Gundo survey. Our main hypothesis was that HIV prevalence is higher in the context of IASGM than in the country as a whole.

**Design:** The ANRS-12339 Sanu Gundo was a cross-sectional survey conducted in December 2015. The quantitative survey consisted in face-to-face administration of questionnaires. Five focus groups were conducted for the qualitative survey. HIV prevalence was calculated for the sample, and according to the type of activity performed in IASGM.

**Settings:** The informal artisanal small-scale gold mining site of Kokoyo, one of the largest sites in Mali (between 6000 and 1000 people).

**Participants:** 224 respondents: 37.5% were gold-diggers, 33% retail traders, 6.7% *tombolomas* (i.e. traditional guards), and 9% female sex-workers. The remaining 13.8% reported another activity (mainly street vending).

#### **BMJ Open**

**Primary and secondary outcome measures:** HIV prevalence and HIV prevalence according to subgroup, as defined by their activity at the Kokoyo IASGM. A Probit logistic regression was implemented to estimate the characteristics associated with HIV seropositivity.

**Results:** HIV prevalence for the total sample was 8% 95%CI[7.7%-8.3%], which is much higher than the 2015 national prevalence of 1.3% (UNAIDS). The probability of HIV seropositivity was 7.8% (p=0.037) higher for female non sex-workers than for any other category, and this probability increased significantly with age. Qualitative data revealed the non-systematic use of condoms with sex-workers; and long distance from health services was the main barrier to accessing care.

**Conclusions**: Integrated policy-making should pay special attention to infectious diseases among populations in IASGM zones. Bringing information/prevention activities closer to people working in gold-mining zones is an urgent public health action.

## Strengths and limitations of this study

- This is the first study conducted in an informal and artisanal small-scale gold mining site in Mali including all of the people directly or indirectly involved in the site's activities.
- This study was implemented using a community-based research approach, the survey design and research questions being developed in collaboration with representatives of the mine of Kokoyo.
- The highest HIV prevalence was found among female non sex-workers (13%), which highlights the importance of focusing on high-risk less-studied populations.
- A large proportion of participants in the survey had never had a HIV test, which highlights the importance of "close proximity health services"
- The cross-sectional design of the Sanu Gundo survey did not enable us to analyse changes over time concerning several socio-economic and behavioural aspects, such as living and working conditions, seasonal mobility, or sexual behaviour

## Introduction

The poverty-driven activities and demographic conditions in the world's informal artisanal small-scale gold mining (IASGM) sector contribute to its vulnerability to infectious diseases including HIV. This disease is recognized as one of the main public health issues in this sector, and potentially concerns almost 15 million people involved in IASGM activities across 70 countries <sup>1</sup>. Despite the high risk of transmission <sup>2,3</sup>, and sustained spread of the disease <sup>4,5</sup>, very little is known about HIV epidemics in IASGM sites. Existing HIV literature on people working and living in gold mining sites mainly focuses on behavioural aspects, such as prevention <sup>6</sup>, attitudes towards voluntary counselling and testing <sup>7,8</sup>,

the link between alcohol consumption and HIV<sup>9</sup>, and the role of gender in the fight against HIV<sup>3,10,11</sup>. Furthermore, most studies have either been conducted among workers in industrial gold mines or in mining communities near gold-bearing zones which are not exclusively related to the IASGM sector. This is also the case of the few studies examining HIV prevalence, which in South Africa in the last decade was measured at approximately 25% <sup>3,12,13</sup>, at 22.3% for a group of Mozambican gold miners in 2012, and at 4.5% and 6.4% for Guinea in 2001 and 2007, respectively <sup>14</sup>. We found only one study concerning an IASGM site, specifically in the Amazon region of Guyana. HIV prevalence there was 6.5% <sup>15</sup>. In addition, these studies principally focus on gold miners themselves and/or other presupposed most-at-risk groups (e.g. female sex-workers), with little attention given to other categories of potentially high-risk people such as gold diggers (i.e. miners working in the informal sector), women who are not sex-workers, and street vendors, all of whom play an important role in the transmission and/or mobility of HIV. Indeed, focusing only on gold miners and not including these other high-risk groups may be detrimental to the fight against HIV<sup>2</sup>, as demonstrated by Clift et al.<sup>16</sup> in a community near two industrial gold-mines in Tanzania, where HIV prevalence was lower in mine workers (6%) than in men and women living at the mines but not directly involved in mining (respectively, 16% and 18%).

Gold mining is one of the cornerstones of the Malian economy, representing almost 70% of the country's total exports and 8% of the GDP in 2013<sup>17–19</sup>. Between 200 000 and 400 000 persons are estimated to be directly concerned by IASGM activities <sup>20,21</sup>. Despite the economic importance of the sector, little attention has been paid to health, as demonstrated by both the poor medical services provided in these sites <sup>22,23</sup> and the increasing demand for health, especially concerning HIV. The high prevalence observed in some key populations provides a picture of the situation people may face in these sites. A demographic and health survey (EDSMV) conducted in Mali in 2012 showed that HIV prevalence among female sex-workers (24.2%), female street vendors (3.7%), and truckers (2.7%) was much higher than the national prevalence of approximately 1.2% in the same year. Different reports on IASGM in Mali have highlighted the urgent need to include the health dimension in economic-based research programs, especially concerning HIV. Community-based activities (e.g., prevention, screening, counselling etc.) could help do this as they could help provide a greater understanding of the heterogeneity of IASGM, the functioning of this informal labour market <sup>2,24</sup>, and the impact of IASGM sector on the transmission and spread of infectious diseases.

We conducted the ANRS-12339 Sanu Gundo survey of the IASGM site at Kokoyo in Mali's Koulikoro region in December 2015, using a community-based research approach. The objective of this article was to estimate HIV prevalence - using the Sanu Gundo survey – in different groups present at Kokoyo, and the factors associated with HIV seropositivity.

#### Methods

#### Design and settings

The ANRS-12339 Sanu Gundo cross-sectional survey was conducted in December 2015 at Kokoyo (for 2 weeks), one of the largest IASGM sites in Mali with a population oscillating between 6 000 and 10 000 people, depending on the season (rainy/dry). In collaboration with the Chamber of Mines and the Mines Ministry, this site was chosen for its geographical location because of the great deal of cultural heterogeneity there. People come not only from other Malian regions, but also from neighbouring countries (Burkina Faso, Guinea, Nigeria, and Niger). All procedures and documents used were validated by both French (CCTIRS N°15.917) and Malian (N°2015/65/CE/FMPOS) ethics committees.

The study started with conversations about global health topics with a focus on HIV/STI prevention which were facilitated by ARCAD-SIDA members. Participants in the conversations were informed about the community-based services provided by the mobile ARCAD-SIDA unit, including the provision of a medical check-up and essential medicines including those for treating STI. Furthermore, ARCAD-SIDA proposed rapid tests for HIV and invited people to take part in the survey. For HIV screening, ARCAD-SIDA follows the Malian Ministry of Health recommendations using Determine® rapid tests, and ImmunoComb® II for confirmation. ARCAD-SIDA provided counselling about the importance of being treated to participants testing HIV positive, and referred them to regional health care centres (Centre de Santé de Référence, CSREF) for blood assessment and inclusion in treatment and follow-up programmes.

Participants in the conversations were then invited to participate in the qualitative and quantitative surveys (they could choose either or both) which formed the basis for the ANRS-12339 Sanu Gundo survey. Community-based agents sent those interested to the Malian team of researchers, who in turn provided detailed information about the content of the survey, its main objectives, and the advantages/risks of participating in this kind of survey. Survey participants provided written formal consent to participate in the survey(s) by signing a letter of consent.

#### Participants

Eligibility criteria included: i) aged 18 years or older; ii) able to speak French, Bambara, or English; iii) able to provide written consent to participate. Persons under the effects of alcohol and/or drugs

were excluded. For the quantitative survey, 224 participants constituted the convenience sample. In order to reduce any potential over-representation and under-representation sampling bias, ARCAD-SIDA activities were conducted every day at different time slots and locations at the site in order to adapt participant recruitment to the work schedule of the different categories of people living there. To those who agreed to participate in the survey(s), a brief face-to-face questionnaire was administered by trained investigators who collected information about the following : i) sociodemographic and socioeconomic characteristics: age (continuous variable), gender, marital status, country of residence, educational level, and weekly earnings (dichotomized at the median of 14 500 FCFA, approximately 24.26 US\$ ) ; ii) type of activity and mobility between sites; iii) HIV awareness, assessed with the following questions: "Have you heard about HIV?" "Have you ever been tested for HIV before today?", "Do you know your HIV status?"; iv) risky behaviours: alcohol and drugs consumption, sexual self-definition, type(s) and frequency of intercourse; v) perceived health status, assessed with the following question: "How do you consider your state of health today?", with possible answers including "very poor", "poor", "moderate", "good", and "very good". This variable was equal to 1 for those perceiving their health was good or very good, and 0 for those perceiving they had poor or very poor health. For the qualitative survey, purposive sampling was implemented. This seemed to be the most suitable sampling method as the main objective of the qualitative survey was to collect information about prevention and access to care for HIV/STI among specific groups. The sample size for each group was fixed between 5 and 8 survey participants in order to ensure diversity among them. Five activity-specific focus groups were organized: Malian gold-diggers, Non-Malian gold-diggers, female sex-workers, female non sex-workers, and people guaranteeing the organizational functioning at the gold mine site (damantiguis and tombolomas).

#### Statistical analyses

The sample was described and HIV prevalence calculated both for the overall sample, and for the different sub-groups listed above (i.e., according to the type of activity in the gold mining site). A Probit logistic regression was implemented to estimate the characteristics associated with the probability of HIV seropositivity. Given the nature of the normal distribution assumption of the error term in the Probit estimation, coefficients are not affected by the presence of extreme values in independent variables. Furthermore, Probit regression allows the computation of marginal effects that are more flexible and more informative than odd-ratios <sup>25,26</sup> which tend to be larger in the presence of rare events and are in any case preferred for small samples<sup>27</sup>. Marginal effects, dF/dX, are interpreted as instantaneous rates of change: for a dichotomous explanatory variable, a marginal

#### **BMJ Open**

effect shows how predicted probabilities change when the variable changes from 0 to 1. All statistical analyses were performed using R software <sup>28</sup>.

#### Qualitative data analysis

Focus groups were audio-recorded and transcribed. The principle of thematic encoding developed by Flick<sup>29</sup> for the analysis of interviews was applied as for other studies with focus groups<sup>30</sup>. Therefore, thematic and pragmatic dimensions were combined into a dialogical unit to highlight patterns specific to the different groups. Lexical analysis was carried out using both Alceste and MAXQDA software. The different dimensions were cross-classified to generate new insights about the organisation of the data (i.e. how common themes are linked together, specific interactions intra-and inter-groups, etc.).

#### Results

#### Sample characteristics

The quantitative survey was conducted on a convenience sample of 224 participants interested in prevention and medical activities provided by ARCAD-SIDA (Table 1): 101 women (45.1%) and 123 men (54.9%). There was a significant difference in average age between both genders: 25 and 29 years old respectively. With respect to participants' main residence, 133 (59.4%) declared they lived in Mali: 28.5% in Kokoyo (i.e. autochthonous) and 71.5% from different cities (i.e. nonautochthonous) including Danga (the nearest) and Timbuktu (the farthest). The remaining 91 participants (40.6%) declared another country as their principal place of residence. With respect to marital status, 158 participants (70.5% of the whole sample) declared they were married or lived in a couple. Among them, 50.6% lived with their spouse in Kokoyo and the remaining 49.4% were geographically single. Of the 86 married/in a couple males who did not live with their spouse in Kokoyo 72.1% declared living with another partner at the site. Conversely, the proportion of geographically single women was only 22.2% among the sample's 72 married/in-a-couple females, and none declared having another partner at the site. Socio-economic difficulties were observed in terms of educational level, with 49.1% of the 224 participants reporting they had never been to school. Among the others, 27.7% and 9.8% had, respectively, a primary and secondary school educational level, 12.1% had a Koranic educational background, and 1.3% declared having postsecondary school education. With respect to their activity in Kokoyo, among the 224 respondents 37.5% were gold-diggers, 33% retail traders, 6.7% tombolomas, 9% female sex-workers, while 14%

reported another activity (mainly street vending). Approximately half of the sample comprised people living under the poverty threshold of 1.9 US\$ per day: 49.3% compared with 49.1% in the general Malian population (2009) <sup>31</sup>. Finally, 11.6% reported mobility between IASGM sites, and declared that Kokoyo was not the first IASGM site where they had worked.

#### HIV prevalence and new diagnoses

Seventeen new HIV-positive cases were found with the ARCAD-SIDA testing, among those tested at the time of the survey, and 1 HIV-positive case was self-reported. Overall, HIV prevalence was 8% 95%CI[4.5%, 11.6%],. HIV prevalence was higher in women than in men, respectively, 10.4 95%CI[4.5%, 16.2%] and 5.9% 95%CI[1.7%, 6.5%]. In terms of the 5 different categories studied, the highest HIV prevalence was in women who were not sex-workers (13% 95%CI[5.4%, 20.3%]). Although lower than in the latter group, the prevalence in female sex-workers was still higher (3.7% 95%CI[-3.5%, 10.9%]) at the Kokoyo site than the national prevalence for sex-workers (irrespective of gender). Prevalence in both non-Malian and Malian male gold-diggers was high, respectively, 7.7% 95%CI[-7.4%, 22.8%] (90%CI[-4.9%, 20.4%]) and 6.5% 95%CI[-0.7%, 13.7%] (90%CI[0.5%, 12.6%]), whereas prevalence in males other than gold diggers was 6.4% 95%CI[-0.7%, 13.5%] (90%CI[0.5%, 12.3%]). No HIV-positive case was observed in traditional guards (*tombolomas*).

The quantitative survey showed that 63.4% participants (142 out of 224) had never had a HIV test. Of these, 7 (4.9%) - 5 women and 2 men - tested positive for HIV using ARCAD-SIDA's test. This corresponded to 38.9% of the total 18 (11 women and 7 men) HIV seropositive participants observed, (or 45.5% (5/11) of total HIV women and 28.6% (2/7) of total HIV men). Among the 5 HIV positive cases for women, 1 was a sand washer, 1 was a female sex-worker and 3 were street vendors. Among the 2 HIV positive cases for men, 1 was a non-Malian gold digger and 1 a male street vendor.

#### Factors associated to HIV seropositivity

A multivariate probit regression was implemented to estimate the factors associated with HIV seropositivity among the 224 participants in the quantitative survey (Table 2). Estimates show that

the probability of HIV seropositivity was 7.8% (p=0.037) higher for female non sex-workers than for any other category, and this probability increased significantly with age. Indeed, the probability of HIV seropositivity - with respect to the youngest participants (aged between 18 and 21 years) – was 14.1% (p=0.034), 14.2% (p=0.036) and 16.1% (p=0.021) higher for participants aged 22-26 years, 27-29 years, and 30+ years, respectively. Finally, a 10.9% lower probability of HIV seropositivity was observed in participants who perceived their health status as good (versus poor).

Table 2. Factors associated with HIV seropositivity among participants living in the informal artisanal smallscale gold mining site (IASGM) of Kokoyo in Mali (n=224)

1 Is the change in the probability given the discrete change for dichotomous variables.

2 Age categories' cut-offs correspond to quartiles.

3 The median weekly earning is 14 500 FCFA (25 US\$). This variable was used to account for the socioeconomic status of participants.

Main findings of the qualitative survey

#### **BMJ Open**

Five focus groups were carried out over 28 participants according to gender and professional status: 6 *tombolomas*, 6 Malian male gold diggers, 5 non-Malian male gold diggers, 5 female sex-workers and 6 women non sex-workers. Among the discourses identified, one referred to sexual practices, especially non-systematic condom use, women sex-workers charging extra for condomless sexual intercourse, and the undisclosed use of condoms by women. Participants attributed these practices to the following factors: i) the place where sexual intercourse took place: bars *versus* the street; ii) the nationality/ethnicity of female sex-workers: Malians and Guineans were seen as more "flexible" than Nigerians (considered as "strict") with regards to condom use; and iii) the nature of the relationship between men and women: trustful relationships (considered "safer") than strictly commercial-sex relationships (considered "risky"). Another discourse identified referred to health services access, with the main barrier being the long distances involved. Other barriers mentioned were the high price of medicines, the lack of specialists and other health care providers, as well as the low number and poor quality of HIV/STI information/prevention programmes described. These barriers were also the main reasons why participants resorted to traditional medicine.

#### Discussion

This is the first study conducted in an informal and artisanal small-scale gold mining site in Mali which investigates HIV not only in those directly involved in informal mining (i.e. gold diggers), but also in other populations with a related activity. The aims of this article were drawn up specifically to respond to the need for the authorities of the IASGM site at Kokoyo to characterize the population living there, and to provide community-based prevention and HIV testing as part of the health care services offered.

The low educational level observed and the high proportion of participants living with revenues below the 1.9 US\$ poverty-line threshold, reflects the high level of poverty reported in the literature concerning IASGM sites in other countries with large gold-bearing zones <sup>22,32</sup>. The fluctuation of the population at Kokoyo suggests large-scale cyclical migration of workers (i.e. they stay for a period, go back home, and the next season they return either to the same mine or to another). Rees et al. suggested they such workers are often separated from their family (i.e. geographically single) <sup>12</sup>, something confirmed by our results where 71.5% of Malian participants came from other regions of Mali (non-autochthonous), and 40.6% of the total sample were not Malian. Moreover, geographically single individuals accounted for 49.4% of the 158 participants who reported being married or living in a couple. This "bridge population" cohabits with other high-risk groups in the IASGM site at Kokoyo, representing a potential source for the continued spread of infectious diseases - including HIV - at

the site, and at their home <sup>4,5</sup>. Indeed, being single (geographically or not) is associated with risky behaviours, given the freedom from social norms and the economic difficulties that prevail in IASGM sites <sup>2</sup>. Furthermore, working conditions and the inherent related dangers which male gold diggers are confronted with, have also been identified as factors related to an increase in risky behaviours <sup>3,33</sup>.

This is the first time that HIV prevalence has been estimated in an IASGM site in Mali. We found a prevalence of 8% in the 224 participants in our study, which is much higher than the Malian national prevalence of 1.3% estimated in 2015<sup>34</sup>, but is in line with the 7% estimated for the IASGM site of Tenkoto in the Kédougou region of Senegal<sup>35</sup>. In addition, HIV prevalence varied for the different categories studied, ranging between 3.6% for female sex-workers to 13% for both women gold diggers and women street vendors. The latter value is in line with the 13% estimated for street vendors in Burkina Faso, although that value was not specific to IASGM sites <sup>36</sup>. Our estimates not only reflect the results from the few qualitative studies performed to date which suggest high prevalence of HIV in IASGM sites, but also highlight that "less classic" groups (i.e. those not directly involved in mining) are at higher risk<sup>2</sup>. The different HIV prevalence rates found across groups may reflect the lack of prevention programs adapted to key populations other than sex-workers in Mali. Most of the efforts in the fight against HIV/AIDS in Mali are concentrated on female sex-workers and men having sex with other men (MSM), who are identified as the most vulnerable groups. This could explain - at least in part - the low prevalence rate among female sex-workers in Kokoyo IASGM and the higher prevalence among other groups, including female non-sex workers and gold-diggers. Indeed participants from these two categories expressed during the focus groups that prevention campaigns are mostly directed at female sex-workers, who seem to be more informed about the risk of HIV contamination and about prevention tools.

The acceptability of HIV testing by participants observed in this study demonstrated not only that the community-based dimension is crucial to conduct this kind of research <sup>2,7</sup>, but that it is also useful for the provision of prevention and HIV testing to this population. Of the 236 persons invited to test for HIV, only 5% refused. This is one of the main contributions of our analysis, and highlights the large demand-supply gap for health care services in Kokoyo. Indeed, the nearest Rural Health Community Centre (CSCOM, *Centre de Santé Communautaire*) does not provide either prevention or testing for HIV, and the only two centres of voluntary testing in the Koulikoro region are far from gold-bearing zones, especially the IASGM site of Kokoyo. This community-based research identified a large number of new HIV positive cases, and this is another important contribution of the study. More specifically, 38% of the 18 HIV-positive participants in the quantitative survey were newly diagnosed using ARCAD-SIDA's rapid tests. Five out of 11 positive cases in women were new diagnoses,

especially female street vendors. Although ARCAD-SIDA referred all 18 HIV positive participants to the nearest regional hospitals (CSREF) in order to link them to care, the emerging question is whether or not these participants subsequently initiated and adhered to antiretroviral treatment given the distance of more than 100km between Kokoyo and Kangaba city where the CSREF is located. Unfortunately, we have no information about lost-to-follow-up rates in people living with HIV in the context of IASGM sites, but presumably these rates are high given that HIV is not of primary concern to people in IASGM sites, as suggested by Campbell <sup>3</sup>. This certainly seems to be the situation in Kokoyo, where the large majority of study participants aware of HIV (over 90%) had never previously gone for a test (63.4%). Multivariate analyses indicated that female non sex-workers, the eldest participants, and those with poor self-perceived health status were the three sub-populations most associated with HIV seropositivity.

Some limitations should be acknowledged. First, the study sample is not representative of the whole population in IASGM sites in Mali. However, our results reflect those in the literature. Second, the cross-sectional design of the Sanu Gundo survey did not enable us to analyse changes over time concerning different aspects, such as living and working conditions, seasonal mobility, and sexual behaviour. Furthermore, although the participants who tested positive for HIV during the study were referred to the regional hospital, the design of the survey did not allow us collect subsequent information, either concerning linkage-to-care or antiretroviral treatment initiation. Finally, there is a possibility of selection bias, as the sample was drawn from the healthcare conversation audience organized by ARCAD-SIDA. Nevertheless, any selection bias would reflect an audience mainly comprising individuals interested in prevention and to some extent, worried about health issues, especially HIV. One would expect that any future study whose design were to attract participants other than those already interested in health care, would result in higher HIV prevalence being measured and would accentuate the precarious characteristics already described by our survey at Kokoyo. Despite these limitations, our study contributes to the existing literature by creating a knowledge base which could be a useful first step for the development of suitable surveys and interventions.

# Conclusion

The results of this study demonstrate the importance of focusing on different categories of workers and the necessity to conduct further similar research on other Malian IASGM sites, in order to account for structural and geographical heterogeneity. The present article contributes to the literature by reopening the debate about the impact of health issues on IASGM activities, especially HIV issues, in a context where the sustained spread of this disease could not only harm efforts in the

fight against AIDS, but also have important negative consequences on one of the main cornerstones of the Malian economy. Integrated policy-making should pay special attention to infectious diseases among populations in IASGM zones. Bringing information/prevention activities closer to people working in gold-bearing zones is an urgent public health action.

## Authors' contribution

LST designed and led the study and wrote the first draft of the report. LST, MSM, BS and BDK designed the analysis. LST, HB and FD analysed the data. MM and MB oversaw data management. All authors critically reviewed and approved the manuscript.

# STROBE 2007 (v4) Statement—Checklist of items that should be included in reports of cross-sectional studies

Section/Topic	ltem #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale 2 Explain the scientific background and rationale for the investigation being reported			
Objectives	3	State specific objectives, including any prespecified hypotheses	3
Methods			
Study design	4	Present key elements of study design early in the paper	4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	4
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	4
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	4
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	NA
Bias	9	Describe any efforts to address potential sources of bias	4
Study size	10	Explain how the study size was arrived at	4
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	4
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	4
		(b) Describe any methods used to examine subgroups and interactions	NA
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	NA
Results			

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	NA
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	5
		(b) Indicate number of participants with missing data for each variable of interest	NA
Outcome data	15*	Report numbers of outcome events or summary measures	6
Main results	16	( <i>a</i> ) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	7
		(b) Report category boundaries when continuous variables were categorized	7
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	NA
Discussion			
Key results	18	Summarise key results with reference to study objectives	8
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	10
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	10
Generalisability	21	Discuss the generalisability (external validity) of the study results	10
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). Information on the STROBE Initiative is available at www.strobe-statement.org.
