

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email editorial.bmjopen@bmj.com

Abstract

Objective The role of cigarette smoking as an independent risk factor for patients with nasopharyngeal carcinoma (NPC) is controversial. We attempted to provide evidence of reliable association between cigarette smoking and the risk of NPC.

Design Meta-analysis.

Data sources PubMed online and the Cochrane Library of relevant studies published up to February 2016.

Eligibility criteria All studies had to evaluated the relationship between NPC and cigarette smoking with nonsmokers as the reference group.

Outcomes The primary outcome was the adjusted OR, RR or HR of NPC patients comparing smoking with nonsmoking; the second was the crude OR, RR or HR.

Results We identified 17 case-control studies and four cohort studies including 5960 NPC cases and 429464 subjects. Compared with never smokers, current smokers and ever smokers had a 59% and a 56% greater risk of NPC respectively. A dose-response relation was identified in that risk estimate rose by 15% ($P<0.001$) with every additional 10 pack-years of smoking, and risk increased with intensity of cigarette smoking (>30 cigarettes per day). Significantly increased risk was only found among male smokers (Odds Ratio (OR), 1.36; 95% confidence interval (CI), 1.15-1.60), not among female smokers (OR, 1.58; 95% CI, 0.99-2.53). This finding also existed in the differentiated (OR, 2.34; 95% CI, 1.77-3.09) and the undifferentiated type of NPC (OR, 1.15; 95% CI, 0.90-1.46). Moreover, people started smoking at younger age (<18 y) had a greater risk for developing NPC (OR, 1.78; 95% CI, 1.41-2.25).

Conclusions Cigarette smoking was associated with increased risk of NPC, especially for young smokers. However, we did not find statistical significant risks of NPC in females and in undifferentiated type, which might warrant further researches.

Strengths and limitations of this study

- Major strengths of our meta-analysis comprise new published studies being included, strict selection criteria, careful literature search, data extraction and analyses by two authors separately.
- The main limitations of our meta-analysis are study design, characteristics and size of study population, different outcome and variables used in eligible studies.

Introduction

There were approximately 86,691 incident cases of NPC and 50,831 NPC-related deaths in 2012 worldwide [1]. Despite NPC is rare in developed countries, the overall incidence rate in Southeastern Asia is 6.5/100,000 person-years among males and 2.6/100,000 person-years among females [2]. Particularly, an age-standardized incidence rate of 20-50 per 100,000 males in south China presented a remarkably high incidence compared to that among white populations [3].

Cigarette smoking has been regarded as a risk factor for occurrence of a wide variety of malignancies, including respiratory tract, gastrointestinal and urogenital systems [4, 5]. Over the decades, some reports have suggested that cigarette smoking is associated with NPC risk [6]. However, the association has not been consistently demonstrated, some studies failed to find such a positive association [7-10]. The discrepancies of inconsistent outcome might be owing to variations in study population, methodology, definitions of cigarette smoking and so on. Furthermore, inevitable recall bias and confounding in case-control studies might further complicate the scenario [11, 12].

One recent meta-analysis of 28 case-control studies and 4 cohort studies reported the adverse effect of cigarette smoking on the incidence of NPC [13]. The pooled analysis showed that ever smokers had a 60% greater risk of developing the disease than never smokers. And there was a significant dose-dependent association. However, between-study heterogeneity was strikingly high across the overall analysis and still remained after stratified analyses. Specifically, some included studies might not be appropriate to be combined for synthetic analysis because of their inadequate reports about association between cigarette smoking and NPC risk [14-17], unclear definition of cigarette smoking and health condition of controls [18, 19], controls with a history of cancer [20], and inappropriate reference group [21, 22]. These might result in overestimating or underestimating the association of cigarette smoking on NPC risk, and thus the conclusions might be hard to interpret. In addition, new studies have been published recently which warrant an up-to-date analysis [23-26].

In this meta-analysis, we sought to provide a summary of available literature of

1
2
3 high quality to examine the association between cigarette smoking and the risk of
4 NPC, we also assessed the gender and histological type differences in effects of
5 cigarette smoking on the NPC risk.
6
7

8 9 **Methods**

10 *Literature search*

11
12 This meta-analysis was performed on the basis of the Meta-analysis Of
13 Observational Studies in Epidemiology (MOOSE) [27]. To identify all relevant
14 publications on NPC and cigarette smoking, firstly, we searched the PubMed and
15 Cochrane Library databases with terms “(((nasopharyngeal carcinoma OR
16 nasopharyngeal cancer OR cancer of nasopharynx)) AND (smoking OR cigarette OR
17 tobacco OR nicotine)) AND (etiology OR epidemiology OR environment OR risk
18 factor) AND (Humans [Mesh])”, then we scrutinized the references of articles
19 obtained from the database search for additional studies. Only publications in English
20 were included.
21
22
23
24
25
26
27
28

29 *Selection criteria*

30
31 The following criteria were applied for literature selection: (1) the study was
32 case-control or cohort design; (2) controls were cancer-free; (3) cases were patients
33 who were histopathologically confirmed NPC and had no other malignances; (4) the
34 study evaluated the relationship between NPC and one of various aspects of cigarette
35 smoking, including cigarette smoking status, smoking intensity, cumulative amount of
36 cigarette smoking, age at onset and duration of smoking; (5) studies used nonsmokers
37 as the reference group; (6) studies provided enough information to estimate the odds
38 ratios (ORs) or the relative risk (RR) or hazard ratios (HRs) with 95% confidence
39 interval (CI) for cigarette smoking variable. If multiple articles were on the same
40 study population, the one with adequate information or most related or largest sample
41 size was finally selected; furthermore, when there were separate data for gender or
42 histologic type of NPC in one study, they were considered for additional subgroup
43 analysis.
44
45
46
47
48
49
50
51
52
53
54
55

56 *Data extraction*

57
58 The following data were extracted from eligible studies: first author, publication
59
60

1
2
3 year, study region, study design, sample size, control source, age of participants
4 (range, mean), gender distribution, categories of smoking (status, intensity, pack-years,
5 age at onset, et al.), method of questionnaire survey, duration of follow-up, end-point
6 (for cohort study), covariates for adjustment, OR, RR or HR with their 95% CIs for
7 each category of smoking exposure. In case the above effect sizes were not available,
8 crude effect estimates and 95% CIs were calculated by provided number of subjects.
9 All data were independently extracted and analyzed by two investigators; any
10 inconsistency was resolved by consensus.
11
12
13
14
15
16
17

18 *Quality assessment*

19
20 The qualities of eligible studies were assessed by using the Newcastle-Ottawa
21 Scale (NOS) [28], which comprised three parts assigned with a maximum of 9 points:
22 selection, comparability, exposures and outcome condition. Two investigators
23 evaluated all eligible publications separately and discrepancies were resolved by
24 discussion.
25
26
27
28

29 *Data integration*

30
31 Not all studies included in this meta-analysis provided consistent information
32 about cigarette smoking, so we stipulated smoking status as follows: ever smokers,
33 current smokers and former smokers. With regard to smoking quantity, we combined
34 data extracted from all eligible publications into new categories: subjects with
35 cigarettes consumption of <30 pack-years were assigned to light smokers, while those
36 who consumed ≥ 30 pack-years were designated to heavy smokers. Similarly, for age
37 at smoking onset, early group meant that subjects began smoking at <18 years old
38 while later group defined as smoking at ≥ 18 years old. We also defined that regions
39 with NPC incidence less than 1 per 100,000 person-years was low incidence rate
40 group, 1-10 per 100,000 person-years was intermediate incidence rate group and
41 greater than 10 per 100,000 was high incidence rate group.
42
43
44
45
46
47
48
49
50
51

52 *Statistical analysis*

53
54 Since NPC is considered as a relatively rare outcome, relative risk and odds ratio
55 were not differentiated, the odds ratios were used as effect size for all studies. We
56 conducted fixed and random effects meta-analyses and the synthetic estimates did not
57
58
59
60

1
2
3 differ substantially between the two models. Therefore, random-effects (Der
4 Simonian-Laird) model [29], generally regarded as the more conservative method,
5 was applied to calculate point estimates for all analyses. Heterogeneity among articles
6 was estimated by using the I^2 statistic and p value associated with Q statistics [30].
7
8

9
10 We conducted dose-response meta-analyses using the generalized least-squares
11 method for trend estimation of summary dose-response data, as described by
12 Greenland and Longnecker [31]. For non-linearity relationship, restricted cubic
13 splines with four knots at percentiles 5%, 35%, 65% and 95% of the distribution were
14 created and P value for non-linearity was computed by testing the null hypothesis that
15 the coefficient of the second and the third splines were equal to zero [32].
16
17
18
19
20
21

22 To assess the robustness of our findings and the source of heterogeneity,
23 meta-regression methods and stratified analyses were performed according to study
24 design, incidence rate of regions, adjustment, score of eligible studies, categories of
25 cigarette smoking, gender and NPC histological type (the latter three were only
26 evaluated in stratified analysis). Sensitivity analysis was also conducted by deleting
27 each study in turn to reflect the influence of every single study to the overall estimate.
28 In addition, we evaluated the publication bias in the pooled analysis by Egger's test
29 and the trim-and-fill method [33]. All statistical analyses were performed with Stata
30 SE 12.0 software, and p value <0.05 (two sides) was considered statistically
31 significant.
32

39

40 *Patient involvement*

41
42 No patients were involved in this study.
43
44

45 **Results**

46 *Study characteristics*

47
48 **Figure 1** shows the flow chart describing the sequential selection procedures of
49 eligible studies. A total of 342 articles were identified, of which 302 articles were
50 deemed irrelevant after reviewing the titles and abstracts. Subsequently, 40 articles
51 were further scanned by full-text. Meanwhile, by searching all references of relevant
52 articles, three additional articles were considered as potentially eligible. Among them
53
54
55
56
57
58 22 were excluded because of following reasons: five studies with inadequate
59
60

1
2
3 information for data extraction, four studies without report of the association between
4 cigarette smoking and NPC risk, four studies with overlapped data, four studies did
5 not designate never smokers as reference group, two studies included improper
6 controls (for example, controls with malignancies or without description of health
7 conditions), one without clear definition of cigarette smoking, one systematic review
8 and one meta-analysis. Finally, 21 articles were eligible for qualitative synthesis,
9 including seventeen case-control studies (5673 cases and 8653 controls) and four
10 cohort studies (287 cases and 420,811 participants).
11
12

13
14
15 All of the studies in the overall analysis were published between 1985 and 2015.
16
17 Of these included studies, not all studies reported the estimates for all risk estimates.
18
19 Nineteen studies reported on ever smoking [7-10, 23, 25, 26, 34-45], ten on former
20 smoking [7-9, 23, 26, 38, 39, 41, 46], eleven on current smoking [7-10, 23, 24, 26, 38,
21 39, 41, 46], ten on pack-years of smoking [7, 23, 24, 26, 35, 37-39, 41, 43] and six on
22 age onset of smoking [7, 9, 10, 23, 26, 46]. Additionally, five studies provided
23 separate data of gender [35, 38, 41-43] and five studies reported the risk of NPC
24 histological type associated with cigarette smoking [9, 38, 39, 42, 44]. As regarding to
25 geographic region, eight studies were conducted in China [7, 8, 24, 26, 37, 41, 43, 44],
26 five in the US [34, 35, 38, 39, 46], five in Southeast Asia region [10, 23, 25, 36, 40],
27 two in Europe [9, 45] and one in Africa [42]. The summarized characteristics of the 21
28 studies are presented in **Tables I and II**.
29
30
31
32
33
34
35
36
37
38
39
40

41 *Association between cigarette smoking status and NPC*

42
43 The pooled analysis of nineteen studies revealed a modest but significant
44 increased risk of NPC among ever smokers against never smokers (OR, 1.56; 95% CI,
45 1.32-1.83). Heterogeneity was obviously observed across the studies ($I^2=66.8\%$,
46 $P<0.01$). The pooled estimate for case-control studies was 1.61 (95% CI, 1.36-1.91;
47 heterogeneity: $I^2=65.8\%$, $P<0.01$), whereas cohort studies presented a null association
48 (OR, 1.11; 95% CI, 0.84-1.48; heterogeneity: $I^2=0.0\%$, $P=0.83$) (**Figure 2**).
49
50
51
52
53

54 Similarly, eleven studies identified for the comparison of current smokers with
55 NPC risk demonstrated positive result (OR, 1.59; 95% CI, 1.35-1.89; heterogeneity:
56 $I^2=32.5\%$, $P=0.14$). When analyzed by study design, the risk estimates were both
57
58
59
60

1
2
3 statistically significant for case-control and cohort studies. The pooled ORs were 1.67
4 (95% CI, 1.06-2.61; heterogeneity: $I^2=22.6\%$, $P=0.25$) and 2.19 (95% CI: 1.02-4.72;
5
6 heterogeneity: $I^2=65.0\%$, $P=0.06$), respectively (**Table III**).

7
8
9 When compared with nonsmokers, former smokers from ten studies exhibited an
10 increased risk of NPC (OR, 1.36; 95% CI, 1.15-1.61; heterogeneity: $I^2=2.3\%$, $P=0.42$).
11 However, stratified analysis presented a void association in cohort studies (OR, 0.87;
12 95% CI, 0.54-1.41; heterogeneity: $I^2=0.0\%$, $P=0.37$) but a significant association in
13 case-control studies (OR, 1.45; 95% CI, 1.21-1.73; heterogeneity: $I^2=0.0\%$, $P=0.70$)
14
15
16
17
18
19 (**Table III**).

20
21 As for age at cigarette smoking onset, six studies reported the association with
22 NPC risk. The pooled analysis revealed that early group (smoking at <18 years old)
23 had significantly increased risk of NPC (OR, 1.78; 95% CI, 1.41-2.25; heterogeneity:
24 $I^2=0.0\%$, $P=0.94$), whereas later group (smoking at ≥ 18 years old) had slightly
25 increased risk of NPC (OR, 1.28; 95% CI, 1.00-1.64; heterogeneity: $I^2=0.0\%$, $P=0.86$)
26
27
28
29
30
31 (**Table III**).

32 *Dose-response analysis*

33
34 For the cumulative amount of cigarette smoking, no between-study heterogeneity
35 was found ($I^2=0.0\%$, $P>0.05$) with a pooled OR of 1.34 (95% CI, 1.13-1.58) for light
36 smokers and 2.03 (95% CI, 1.57-2.61) for heavy smokers, respectively (**Table III**).
37 The dose-response analysis showed statistical linear relationship between the
38 cumulative number of pack-years and NPC risk ($P_{\text{for linearity}}=0.83$) (**Figure 3**).
39 Smokers had a 15% (OR, 1.15; 95% CI, 1.11-1.19, $P<0.001$) increasing risk of NPC
40 for every additional 10 pack-years smoked in comparison with never smokers (data
41 not shown). When comparing the NPC risk for intensity of cigarettes smoked per day
42 with nonsmokers, the non-linear dose-response relationship indicated that smokers
43 with high exposure (>30 cigarettes/day) other than with low exposure have higher risk
44 estimate, which presented an upward tendency in steeply rising trend (P_{for}
45 non-linearity<0.05) (**Figure 4**).

56 *Stratified analysis*

57
58 When conducted stratified analysis by regions with different incidence rate, there
59
60

1
2
3 were nineteen studies compared NPC risk for ever smokers with that for never
4 smokers. Among them, five studies carried out in regions with low NPC incidence
5 rate yielded the highest risk (OR, 1.68; 95% CI, 1.36-2.07; heterogeneity: $I^2=0.0\%$,
6 $P=0.84$). The pooled estimates were 1.59 (95% CI, 1.21-2.09; heterogeneity:
7 $I^2=78.8\%$, $P<0.01$) for regions (ten studies) with intermediate NPC incidence rate and
8 1.27 (95% CI, 1.05-1.53; heterogeneity: $I^2=0.0\%$, $P=0.52$) for regions (4 studies) with
9 high incidence rate, respectively (**Table III**).

10
11 We also performed stratified analysis by status of adjustment for confounding
12 variables. Thirteen studies provided adjusted ORs for pooled analysis. But six studies
13 either reported unadjusted ORs or reported the number of cases and controls which
14 could be used to calculate the odds ratios. The estimates for the association of
15 cigarette smoking and NPC risk in adjusted group (OR, 1.55; 95% CI, 1.26-1.91;
16 heterogeneity: $I^2=75.3\%$, $P<0.01$) and in unadjusted group (OR, 1.57, 95% CI,
17 1.27-1.93; heterogeneity: $I^2=0.0\%$, $P=0.68$) were similar (**Table III**).

18
19 When the meta-regression analyses were applied to assess the sources of
20 heterogeneity and their impacts on the NPC risk, we found that the publication year,
21 study design, regions of different incidence rate and quality of studies were not
22 significant sources of heterogeneity ($P=0.55$, data not shown).

23 24 25 *Association between cigarette smoking and histological type of NPC*

26
27 Specifically, the effects of cigarette smoking on NPC histological types were
28 different. We found that significant association was only noted for differentiated
29 squamous-cell NPC (OR, 2.34; 95% CI, 1.77-3.09; heterogeneity: $I^2=0.0\%$, $P=0.72$).
30 Contrarily, the risk estimate for undifferentiated carcinoma of NPC in smokers was
31 pointless in terms of statistics though the odds ratio was 1.15 (95% CI, 0.90-1.46;
32 heterogeneity: $I^2=0.0\%$, $P=0.02$) (**Table III**).

33 34 35 *Association between cigarette smoking of gender and NPC*

36
37 Seven studies addressed the association between cigarette smoking and NPC risk
38 by gender, including five in males and two in females. Compared with never smokers,
39 increased risk for male smokers was noted (OR, 1.36; 95% CI, 1.15-1.60). However,
40 an insignificant association (OR, 1.58; 95% CI, 0.99-2.53) was observed for female
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 smokers (**Table III**).

4
5 *Sensitivity analysis and publication bias*

6
7 Sensitivity analysis revealed that Ji 2011 study [42] was the source of statistical
8 heterogeneity in the pooled analysis for ever smokers. When this outlier study was
9 removed, between-study heterogeneity dropped strikingly to 27.3% in the remaining
10 studies, whereas the odds ratios (OR, 1.47; 95% CI, 1.31-1.66) changed moderately
11 but remained significant. As for case-control studies, the OR changed from 1.61 (95%
12 CI: 1.36-1.91) to 1.52 (95% CI: 1.35-1.72) with heterogeneity fallen from 65.8% to
13 23.5% (**Figure 5**). The findings were further verified in the intermediated incidence
14 rate group (OR, 1.49, 95% CI, 1.21-1.82; heterogeneity: $I^2=49.6%$, $P=0.04$) and in the
15 adjusted group (OR, 1.45; 95% CI, 1.25-1.69; heterogeneity: $I^2=41.8%$, $P=0.05$) (data
16 not shown).
17
18
19
20
21
22
23
24
25

26 Publication bias was evaluated by Egger's test and Trim-and-Fill method. Except
27 for subgroup analyses with ever smokers and heavy smokers, no prominently
28 significant publication bias (with $P>0.05$ in Egger's test) was observed in our
29 meta-analysis. After adjusted for publication bias, the risk of NPC remained stable
30 with an OR of 1.56 (95% CI, 1.32-1.84) for ever smokers, but changed slightly (OR,
31 1.80, 95% CI, 1.37-2.36) for heavy smokers (**Table III**).
32
33
34
35
36

37 **Discussion**

38
39 The results from this meta-analysis, based on seventeen case-control studies and
40 four cohort studies, supported that there was moderate association between cigarette
41 smoking and nasopharyngeal carcinoma risk, which was consistent with the result of
42 previous meta-analysis [13].
43
44
45
46

47 *Interpretation*

48
49 The pooled risk estimate for cohort studies comparing ever smokers to never
50 smokers was not statistically significant. When conducted similar stratified analyses
51 for current smokers and former smokers, we found that current smoking was
52 significantly related to the risk of NPC while former smoking had an insignificant
53 association with NPC risk. Considering the findings of stratified analyses, it might be
54 the result from former smoking that contributed to the discrepancy between pooled
55
56
57
58
59
60

1
2
3 analysis for cohort studies and overall analysis. In addition, this meta-analysis
4 demonstrated relatively high heterogeneity both for the overall analysis and subgroup
5 analyses. When the Ji 2011 study [44] was removed from the synthetic analysis,
6 heterogeneity was strikingly reduced in stratified analysis by study design and regions
7 with different NPC incidence rate. Furthermore, the meta-regression analyses
8 indicated that heterogeneity did not prominently result from publication year, study
9 design, regions of different incident rate and quality of studies. To our knowledge,
10 multiple lines of epidemiological studies had found that the development of NPC
11 could be influenced by varieties of etiologies including Epstein-Barr virus (EBV),
12 genetic components and other environmental factors, like preserved food,
13 socioeconomic status, occupation, so on and so forth [6, 47-50]. Therefore, it might be
14 its inappropriate subjects that contributed to selection bias which resulted in the high
15 heterogeneity in the Ji 2011 study, though it had a large sample size with risk
16 estimates adjusted by age, gender, alcohol intake and family history.

29

30 One large cohort study [10], conducted in high-incidence region and comprised
31 the majority of undifferentiated NPC (nearly 90% cases), did not reported statistically
32 increased risk of NPC among current smokers compared with never smokers. The
33 difference in the effect of current smoking on NPC risk may be due to its histological
34 type of NPC because undifferentiated carcinoma in high-risk areas seemed more
35 strongly related to Epstein-Barr virus infection other than cigarette smoking [48].
36 Meanwhile, some case-control studies with small sample size of current smokers also
37 had null results [7-9, 38, 39], of which two studies pointed out that significantly
38 higher risk only existed for smokers with considerable levels of cigarette smoking
39 (>20 cigarettes/day or >30 pack-years) [38, 39]. Nonetheless, the result of our
40 integrated analysis for current smokers versus never smokers was generally consistent
41 with that of the previous meta-analyses [13].
42
43
44
45
46
47
48
49
50
51

52 For former smokers, the less consistent risk estimates might result from small
53 number of studies with adequate sample size. The estimates for former smokers in
54 eight studies [7-10, 26, 39, 41, 46] presented null association on NPC risk which was
55 parallel to the results of stratified analysis by study design, and only two studies [23,
56
57
58
59
60

1
2
3 38] demonstrated statistically positive results. The discrepancies in the effects of
4 former cigarette smoking on NPC risk might arise from the following aspects: the
5 group of former smokers may have included people who had quit for a long time, and
6 thus their risk might diminish or even reach the level of never smokers; the minimum
7 period of time since quitting smoking in former smokers varied by study, which could
8 result in judgement bias on the interviewed subjects in some studies.
9

10
11
12
13
14
15 This meta-analysis revealed that there was a clear dose-response relationship
16 between cigarette smoking and the risk of NPC. That is, the more cigarette smoking
17 (intensity of cigarettes smoked per day and the cumulative amount of pack-years), the
18 higher risk for the development of NPC. Note that similar results have been widely
19 observed for pancreatic cancer, liver cancer, renal carcinoma and gallbladder disease
20 [51-54]. The exact explanation of this dose-dependent effect remains vague, it could
21 be hypothesized that the more cigarette smoking, the greater impact on the epithelial
22 cells of nasopharynx. Therefore, the risk of NPC would be higher in those who
23 smoked more cigarettes. The actual mechanism about the relationship of the amount
24 of smoking and NPC risk had been searched by molecular studies [55, 56], which
25 pointed out that smoking is a factor for tumor growth and acts as a mutagen and DNA
26 damaging agent that drives tumor initiation in normal epithelial cells of nasopharynx.
27

28
29
30
31
32
33
34
35
36
37 In this analysis, a statistically significant effect of smoking on NPC risk was
38 observed in males but not in females. The gender difference in response to smoking
39 might be related to interaction between protective endogenous or exogenous estrogens
40 among women compared with men [57], and could also be explained by maturity of
41 smoking trends among males and but not among females. Men might exposure to
42 smoking for a longer duration as compared to women (34% of the male vs. 11% of the
43 female had started smoking before the age of 15 years) [58]. However, the result of
44 female ever smokers might not be adequately stable because only two studies reported
45 the association between cigarette smoking and the risk of NPC for females [35, 41].
46
47
48
49
50
51
52
53

54
55 Additionally, we found that the younger age people began to smoke, the higher
56 risk they developed NPC. Our results showed that the pooled ORs were 1.78 (95% CI,
57 1.41-2.25) for smokers in early group and 1.28 (95% CI, 1.00-1.64) in later group,

respectively. Interestingly, the findings of previous meta-analysis appeared totally opposite with ORs of 1.17 (95% CI, 0.78-1.75) for early group and 1.58 (95% CI, 1.10-2.26) for later group [13]. Like many other cancers, NPC may take decades to develop from premalignant cells to detectable solid tumor. Thus, the exposure to carcinogenic agents early in life could have substantial impacts on the development of NPC [6, 59]. Moreover, the incidence of NPC peaks at age of 50-59 years in high-risk regions, while in western countries, the incidence of NPC peaks somewhat later (≥ 65 -year-olds) [59]. As a result, the number of NPC patients in terms of age distribution could considerably vary in our eligible studies that were conducted in different countries.

When stratified by histological type of NPC, the pooled analysis presented a higher risk of differentiated NPC than that of undifferentiated NPC, and the later had an insignificant risk estimate. This difference might be owing to fewer studies included in the pooled analysis for undifferentiated NPC because we excluded those ineligible studies either for no report of the association between cigarette smoking and NPC risk [16] or for overlapped data [60]. It might avoid incorrect estimation of smoking effects on NPC risk. Moreover, we found that the risk estimates adversely associated with the NPC incidence rate. For example, the pooled OR for high incidence rate areas to low incidence rate areas ranged from 1.27 to 1.68. This might suggest there are substantial heterogeneity between NPC risk and smoking by histological types and geographic variations. Undifferentiated carcinoma of the nasopharynx is the predominant type in high-risk areas, and it is consistently associated with EBV infection, which may increase the carcinogenic effect of cigarette smoking [48].

Generalizability

The magnitude of association between cigarette smoking and the NPC risk was not as big as those for other smoking-related cancers like lung cancer and gastrointestinal malignancies [4]. However, NPC was quite epidemic in southeastern Asia especially in cities in southern China, and China was one of the largest tobacco producing and consuming countries in the world [61]. Besides, we found current

1
2
3 smokers are more related to the development of NPC with a higher risk estimate as
4 compared to former smokers. These emphasized the importance and urgency of
5 efforts to initiate the control of cigarette smoking to improve public health. Any
6 efficient tobacco control programs would be helpful to reduce morbidity and mortality
7 of smoking-related cancers worldwide.
8
9

10 11 12 **Limitations**

13
14 The results of this meta-analysis should be explicated in the context of several
15 limitations. For example, the design of included studies varied in source of subjects
16 recruited, standardization for categories of cigarette smoking, in adjusted factors.
17 Additionally, our meta-analysis was a mix of retrospective studies and prospective
18 studies, and was lack of individual participant data for adjustment of potential
19 confounders. Generally, Epstein-Barr virus infection was thought to be highly related
20 to NPC risk [62]. However, a 22-year follow-up study carried out by Hsu et al.
21 revealed that Epstein-Barr virus was less likely to modify the estimate for smoking
22 associated with NPC risk [43]. And the links of other risk factors like dietary and
23 social practices were often inconsistent between studies [62]. Moreover, the risk
24 estimates of NPC resembled both in the group with adjusted odds ratio and in the
25 group with unadjusted odds ratio in our meta-analysis.

35
36

37 **Conclusions**

38
39 This meta-analysis demonstrated that cigarette smoking associated with a modest,
40 but statistically significant increased risk of NPC. Yet, further prospective studies are
41 needed to elucidate the NPC risk in terms of gender, histological type, and for former
42 smokers and smoking onset age.

MOOSE Checklist for Meta-analyses of Observational Studies

Item No	Recommendation	Reported on Page No
Reporting of background should include		
1	Problem definition	4
2	Hypothesis statement	5
3	Description of study outcome(s)	5
4	Type of exposure or intervention used	4
5	Type of study designs used	4
6	Study population	8
Reporting of search strategy should include		
7	Qualifications of searchers (eg, librarians and investigators)	None
8	Search strategy, including time period included in the synthesis and key words	5
9	Effort to include all available studies, including contact with authors	5
10	Databases and registries searched	5
11	Search software used, name and version, including special features used (eg, explosion)	5
12	Use of hand searching (eg, reference lists of obtained articles)	5
13	List of citations located and those excluded, including justification	7
14	Method of addressing articles published in languages other than English	5
15	Method of handling abstracts and unpublished studies	7
16	Description of any contact with authors	None
Reporting of methods should include		
17	Description of relevance or appropriateness of studies assembled for assessing the hypothesis to be tested	5
18	Rationale for the selection and coding of data (eg, sound clinical principles or convenience)	5
19	Documentation of how data were classified and coded (eg, multiple raters, blinding and interrater reliability)	6
20	Assessment of confounding (eg, comparability of cases and controls in studies where appropriate)	6
21	Assessment of study quality, including blinding of quality assessors, stratification or regression on possible predictors of study results	6
22	Assessment of heterogeneity	7
23	Description of statistical methods (eg, complete description of fixed or random effects models, justification of whether the chosen models account for predictors of study results, dose-response models, or cumulative meta-analysis) in sufficient detail to be replicated	6
24	Provision of appropriate tables and graphics	7
Reporting of results should include		
25	Graphic summarizing individual study estimates and overall estimate	8
26	Table giving descriptive information for each study included	20
27	Results of sensitivity testing (eg, subgroup analysis)	9
28	Indication of statistical uncertainty of findings	11

Item No	Recommendation	Reported on Page No
Reporting of discussion should include		
29	Quantitative assessment of bias (eg, publication bias)	12, 14
30	Justification for exclusion (eg, exclusion of non-English language citations)	None
31	Assessment of quality of included studies	12
Reporting of conclusions should include		
32	Consideration of alternative explanations for observed results	15
33	Generalization of the conclusions (ie, appropriate for the data presented and within the domain of the literature review)	14
34	Guidelines for future research	15
35	Disclosure of funding source	16

STROBE Statement—checklist of items that should be included in reports of observational studies

	Item No	Recommendation
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract Page 1 (b) Provide in the abstract an informative and balanced summary of what was done and what was found Page 2
Introduction		
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported: Page 4
Objectives	3	State specific objectives, including any prespecified hypotheses Page 4-5
Methods		
Study design	4	Present key elements of study design early in the paper Page 1-2
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection Page 5-7
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants (b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case Page 6 and Table 1&2
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group Page 5
Bias	9	Describe any efforts to address potential sources of bias Page 3
Study size	10	Explain how the study size was arrived at Page 2 or 7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why Page 5-6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding (b) Describe any methods used to examine subgroups and interactions (c) Explain how missing data were addressed (d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy (e) Describe any sensitivity analyses Page 6-7

Results

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed (b) Give reasons for non-participation at each stage (c) Consider use of a flow diagram Page 7-8
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders (b) Indicate number of participants with missing data for each variable of interest (c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount) Page 8
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time <i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure <i>Cross-sectional study</i> —Report numbers of outcome events or summary measures Page 7-8
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included (b) Report category boundaries when continuous variables were categorized (c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period Page 8-11
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses Page 10-11

Discussion

Key results	18	Summarise key results with reference to study objectives Page 11-14
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias Page 15
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence Page 11-14
Generalisability	21	Discuss the generalisability (external validity) of the study results Page 14-15

Other information

Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based Page 16
---------	----	--

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.

Abstract

Objective The role of cigarette smoking as an independent risk factor for patients with nasopharyngeal carcinoma (NPC) is controversial. We attempted to provide evidence of a reliable association between cigarette smoking and the risk of NPC.

Design Meta-analysis.

Data sources PubMed online and the Cochrane Library of relevant studies published up to February 2016.

Eligibility criteria All studies had to evaluate the relationship between NPC and cigarette smoking with never smokers as the reference group.

Outcomes The primary outcome was the adjusted OR, RR or HR of NPC patients comparing smoking with never-smoking; the second was the crude OR, RR or HR.

Results We identified 17 case-control studies and four cohort studies including 5960 NPC cases and 429464 subjects. Compared with never smokers, current smokers and ever smokers had a 59% and a 56% greater risk of NPC respectively. A dose-response relation was identified in that the risk estimate rose by 15% ($P<0.001$) with every additional 10 pack-years of smoking, and risk increased with intensity of cigarette smoking (>30 cigarettes per day). Significantly increased risk was only found among male smokers (Odds Ratio (OR), 1.36; 95% confidence interval (CI), 1.15-1.60), not among female smokers (OR, 1.58; 95% CI, 0.99-2.53). Significantly increased risk also existed in the differentiated (OR, 2.34; 95% CI, 1.77-3.09) and the undifferentiated type of NPC (OR, 1.15; 95% CI, 0.90-1.46). Moreover, people started smoking at younger age (<18 y) had a greater risk than those starting later for developing NPC (OR, 1.78; 95% CI, 1.41-2.25).

Conclusions Cigarette smoking was associated with increased risk of NPC, especially for young smokers. However, we did not find statistical significant risks of NPC in females and in undifferentiated type, which might warrant further researches.

Strengths and limitations of this study

- Major strengths of our meta-analysis comprise new published studies being included, strict selection criteria, careful literature search, data extraction and analyses by two authors separately.
- The main limitations of our meta-analysis are study design, characteristics and size of study population, different outcome and variables used in eligible studies.

Introduction

There were approximately 86,691 incident cases of NPC and 50,831 NPC-related deaths in 2012 worldwide [1]. Despite NPC being rare in developed countries, the overall incidence rate in Southeastern Asia is 6.5/100,000 person-years among males and 2.6/100,000 person-years among females [2]. Particularly, an age-standardized incidence rate of 20-50 per 100,000 males in south China presented a remarkably high incidence compared to that among white populations [3].

Cigarette smoking has been regarded as a risk factor for the occurrence of a wide variety of malignancies, including respiratory tract, gastrointestinal and urogenital systems [4, 5]. Over the decades, some reports have suggested that cigarette smoking is associated with NPC risk [6]. However, the association has not been consistently demonstrated, some studies failing to find such a positive association [7-10]. The discrepancies of inconsistent outcome might be owing to variations in study population, methodology, definitions of cigarette smoking and so on. Furthermore, inevitable recall bias and confounding in case-control studies might further complicate the scenario [11, 12].

One recent meta-analysis of 28 case-control studies and 4 cohort studies reported the adverse effect of cigarette smoking on the incidence of NPC [13]. The pooled analysis showed that ever smokers had a 60% greater risk of developing the disease than never smokers. And there was a significant dose-dependent association. However, between-study heterogeneity was strikingly high across the overall analysis and still remained after stratified analyses. Specifically, some included studies might not be appropriate to be combined for synthetic analysis because of their inadequate reports about association between cigarette smoking and NPC risk [14-17], unclear definition of cigarette smoking and health condition of controls [18, 19], controls with a history of cancer [20], and inappropriate reference group [21, 22]. These might result in overestimating or underestimating the association of cigarette smoking on NPC risk, and thus the conclusions might be hard to interpret. In addition, new studies have been published recently which warrant an up-to-date analysis [23-26].

In this meta-analysis, we sought to provide a summary of available literature to

1
2
3 examine the association between cigarette smoking and the risk of NPC, we also
4 assessed the gender and histological type differences in effects of cigarette smoking
5 on the NPC risk.
6
7

8 **Methods**

9 *Literature search*

10
11 This meta-analysis was performed on the basis of the Meta-analysis Of
12 Observational Studies in Epidemiology (MOOSE) [27]. To identify all relevant
13 publications on NPC and cigarette smoking, firstly, we used the engine “Windows
14 Internet Explorer 10.0” to search the PubMed and Cochrane Library databases with
15 terms “(((nasopharyngeal carcinoma OR nasopharyngeal cancer OR cancer of
16 nasopharynx)) AND (smoking OR cigarette OR tobacco OR nicotine)) AND (etiology
17 OR epidemiology OR environment OR risk factor) AND (Humans [Mesh])”, then we
18 scrutinized the references of articles obtained from the database search for additional
19 studies. Only publications in English were included.
20
21
22
23
24
25
26
27
28

29 *Selection criteria*

30
31 The following criteria were applied for literature selection: (1) the study was
32 case-control or cohort design; (2) controls were cancer-free; (3) cases were patients
33 who were histopathologically confirmed NPC and had no other malignances; (4) the
34 study evaluated the relationship between NPC and one of various aspects of cigarette
35 smoking, including cigarette smoking status, smoking intensity, cumulative amount of
36 cigarette smoking, age at onset and duration of smoking; (5) studies used never
37 smokers as the reference group; (6) studies provided enough information to estimate
38 the odds ratios (ORs) or the relative risk (RR) or hazard ratios (HRs) with 95%
39 confidence interval (CI) for cigarette smoking variable. If multiple articles were on
40 the same study population, the one with adequate information or most related or
41 largest sample size was finally selected; furthermore, when there were separate data
42 for gender or histologic type of NPC in one study, they were considered for additional
43 subgroup analysis.
44
45
46
47
48
49
50
51
52
53
54

55 *Data extraction*

56
57 The following data were extracted from eligible studies: first author, publication
58
59

1
2
3 year, study region, study design, sample size, control source, age of participants
4 (range, mean), gender distribution, categories of smoking (status, intensity, pack-years,
5 age at onset of smoking, et al.), method of questionnaire survey, duration of follow-up,
6 end-point (for cohort study), covariates for adjustment, OR, RR or HR with their 95%
7 CIs for each category of smoking exposure. In case the above effect sizes were not
8 available, crude effect estimates and 95% CIs were calculated by provided number of
9 subjects. All data were independently extracted and analyzed by two investigators;
10 any inconsistency was resolved by consensus.
11
12
13
14
15
16
17

18 *Quality assessment*

19
20 The qualities of eligible studies were assessed by using the Newcastle-Ottawa
21 Scale (NOS) [28], which comprised three parts assigned with a maximum of 9 points:
22 selection, comparability, exposures and outcome condition. Two investigators
23 evaluated all eligible publications separately and discrepancies were resolved by
24 discussion.
25
26
27
28

29 *Data integration*

30
31 Not all studies included in this meta-analysis provided consistent information
32 about cigarette smoking, so we stipulated smoking status as follows: never smokers
33 (people that did not smoke any tobacco product), ever smokers, current smokers and
34 former smokers. With regard to smoking quantity, we combined data extracted from
35 all eligible publications into new categories: subjects with cigarettes consumption of
36 <30 pack-years were assigned to light smokers, while those who consumed ≥ 30
37 pack-years were designated to heavy smokers. Similarly, for age at smoking onset,
38 early group meant that subjects began smoking at <18 years old while later group
39 defined as smoking at ≥ 18 years old. We also defined that regions with NPC incidence
40 less than 1 per 100,000 person-years was low incidence rate group, 1-10 per 100,000
41 person-years was intermediate incidence rate group and greater than 10 per 100,000
42 was high incidence rate group.
43
44
45
46
47
48
49
50
51
52
53

54 *Statistical analysis*

55
56 Since NPC is considered as a relatively rare outcome, relative risk and odds ratio
57 were not differentiated, the odds ratios were used as effect size for all studies. We
58
59
60

1
2
3 conducted fixed and random effects meta-analyses and the synthetic estimates did not
4 differ substantially between the two models. Therefore, random-effects (Der
5 Simonian-Laird) model [29], generally regarded as the more conservative method,
6 was applied to calculate point estimates for all analyses. Heterogeneity among articles
7 was estimated by using the I^2 statistic and p value associated with Q statistics [30].
8
9

10
11 We conducted dose-response meta-analyses using the generalized least-squares
12 method for trend estimation of summary dose-response data, as described by
13 Greenland and Longnecker [31]. For non-linearity relationship, restricted cubic
14 splines with four knots at percentiles 5%, 35%, 65% and 95% of the distribution were
15 created and P value for non-linearity was computed by testing the null hypothesis that
16 the coefficient of the second and the third splines were equal to zero [32].
17
18
19
20
21
22
23

24 To assess the robustness of our findings and the source of heterogeneity,
25 meta-regression methods and stratified analyses were performed according to study
26 design, incidence rate of regions, adjustment, score of eligible studies, categories of
27 cigarette smoking, gender and NPC histological type (the latter three were only
28 evaluated in stratified analysis). Sensitivity analysis was also conducted by deleting
29 each study in turn to reflect the influence of every single study to the overall estimate.
30 In addition, we evaluated the publication bias in the pooled analysis by Egger's test
31 and the trim-and-fill method [33]. All statistical analyses were performed with Stata
32 SE 12.0 software, and p value <0.05 (two sides) was considered statistically
33 significant.

22 were excluded because of following reasons: five studies with inadequate information for data extraction, four studies without report of the association between cigarette smoking and NPC risk, four studies with overlapped data, four studies did not designate never smokers as reference group, two studies included improper controls (for example, controls with malignancies or without description of health conditions), one without clear definition of cigarette smoking, one systematic review and one meta-analysis. Finally, 21 articles were eligible for qualitative synthesis, including seventeen case-control studies (5673 cases and 8653 controls) and four cohort studies (287 cases and 420,811 participants).

All of the studies in the overall analysis were published between 1985 and 2015. Of these included studies, not all studies reported the estimates for all risk estimates. Nineteen studies reported on ever smoking [7-10, 23, 25, 26, 34-45], ten on former smoking [7-9, 23, 26, 38, 39, 41, 46], eleven on current smoking [7-10, 23, 24, 26, 38, 39, 41, 46], ten on pack-years of smoking [7, 23, 24, 26, 35, 37-39, 41, 43] and six on age at onset of smoking [7, 9, 10, 23, 26, 46]. Additionally, five studies provided separate data of gender [35, 38, 41-43] and five studies reported the risk of NPC histological type associated with cigarette smoking [9, 38, 39, 42, 44]. As regarding to geographic region, eight studies were conducted in China [7, 8, 24, 26, 37, 41, 43, 44], five in the US [34, 35, 38, 39, 46], five in Southeast Asia region [10, 23, 25, 36, 40], two in Europe [9, 45] and one in Africa [42]. The summarized characteristics of the 21 studies are presented in **Tables I and II**.

Association between cigarette smoking status and NPC

The pooled analysis of nineteen studies revealed a modest but significant increased risk of NPC among ever smokers against never smokers (OR, 1.56; 95% CI, 1.32-1.83). Heterogeneity was obviously observed across the studies ($I^2=66.8\%$, $P<0.01$). The pooled estimate for case-control studies was 1.61 (95% CI, 1.36-1.91; heterogeneity: $I^2=65.8\%$, $P<0.01$), whereas cohort studies presented a null association (OR, 1.11; 95% CI, 0.84-1.48; heterogeneity: $I^2=0.0\%$, $P=0.83$) (**Figure 2**).

Similarly, eleven studies identified for the comparison of current smokers with NPC risk demonstrated positive result (OR, 1.59; 95% CI, 1.35-1.89; heterogeneity:

$I^2=32.5\%$, $P=0.14$). When analyzed by study design, the risk estimates were both statistically significant for case-control and cohort studies. The pooled ORs were 1.67 (95% CI, 1.06-2.61; heterogeneity: $I^2=22.6\%$, $P=0.25$) and 2.19 (95% CI: 1.02-4.72; heterogeneity: $I^2=65.0\%$, $P=0.06$), respectively (**Table III**).

When compared with never smokers, former smokers from ten studies exhibited an increased risk of NPC (OR, 1.36; 95% CI, 1.15-1.61; heterogeneity: $I^2=2.3\%$, $P=0.42$). However, stratified analysis presented a void association in cohort studies (OR, 0.87; 95% CI, 0.54-1.41; heterogeneity: $I^2=0.0\%$, $P=0.37$) but a significant association in case-control studies (OR, 1.45; 95% CI, 1.21-1.73; heterogeneity: $I^2=0.0\%$, $P=0.70$) (**Table III**).

As for age at cigarette smoking onset, six studies reported the association with NPC risk. The pooled analysis revealed that early group (smoking at <18 years old) had significantly increased risk of NPC (OR, 1.78; 95% CI, 1.41-2.25; heterogeneity: $I^2=0.0\%$, $P=0.94$), whereas later group (smoking at ≥ 18 years old) had slightly increased risk of NPC (OR, 1.28; 95% CI, 1.00-1.64; heterogeneity: $I^2=0.0\%$, $P=0.86$) (**Table III**).

Dose-response analysis

For the cumulative amount of cigarette smoking, no between-study heterogeneity was found ($I^2=0.0\%$, $P>0.05$) with a pooled OR of 1.34 (95% CI, 1.13-1.58) for light smokers and 2.03 (95% CI, 1.57-2.61) for heavy smokers, respectively (**Table III**). The dose-response analysis showed statistical linear relationship between the number of pack-years and NPC risk ($P_{\text{for linearity}}=0.83$) (**Figure 3**). Smokers had a 15% (OR, 1.15; 95% CI, 1.11-1.19, $P<0.001$) increasing risk of NPC for every additional 10 pack-years smoked in comparison with never smokers (data not shown). When comparing the NPC risk for intensity of cigarettes smoked per day with never smokers, the non-linear dose-response relationship indicated that smokers with high exposure (>30 cigarettes/day) other than with low exposure have higher risk estimate, which presented an upward tendency in steeply rising trend ($P_{\text{for non-linearity}}<0.05$) (**Figure 4**).

Stratified analysis

When conducted stratified analysis by regions with different incidence rate, there

1
2
3 were nineteen studies compared NPC risk for ever smokers with that for never
4 smokers. Among them, five studies carried out in regions with low NPC incidence
5 rate yielded the highest risk (OR, 1.68; 95% CI, 1.36-2.07; heterogeneity: $I^2=0.0\%$,
6 $P=0.84$). The pooled estimates were 1.59 (95% CI, 1.21-2.09; heterogeneity:
7 $I^2=78.8\%$, $P<0.01$) for regions (ten studies) with intermediate NPC incidence rate and
8 1.27 (95% CI, 1.05-1.53; heterogeneity: $I^2=0.0\%$, $P=0.52$) for regions (4 studies) with
9 high incidence rate, respectively (**Table III**).

10
11 We also performed stratified analysis by status of adjustment for confounding
12 variables. Thirteen studies provided adjusted ORs for pooled analysis. But six studies
13 either reported unadjusted ORs or reported the number of cases and controls which
14 could be used to calculate the odds ratios. The estimates for the association of
15 cigarette smoking and NPC risk in adjusted group (OR, 1.55; 95% CI, 1.26-1.91;
16 heterogeneity: $I^2=75.3\%$, $P<0.01$) and in unadjusted group (OR, 1.57, 95% CI,
17 1.27-1.93; heterogeneity: $I^2=0.0\%$, $P=0.68$) were similar (**Table III**).

18
19 When the meta-regression analyses were applied to assess the sources of
20 heterogeneity and their impacts on the NPC risk, we found that the publication year,
21 study design, regions of different incidence rate and quality of studies were not
22 significant sources of heterogeneity ($P=0.55$, data not shown).

23 24 25 *Association between cigarette smoking and histological type of NPC*

26
27 Specifically, the effects of cigarette smoking on NPC histological types were
28 different. We found that significant association was only noted for differentiated
29 squamous-cell NPC (OR, 2.34; 95% CI, 1.77-3.09; heterogeneity: $I^2=0.0\%$, $P=0.72$).
30 Contrarily, the risk estimate for undifferentiated carcinoma of NPC in smokers was
31 statistically insignificant though the odds ratio was 1.15 (95% CI, 0.90-1.46;
32 heterogeneity: $I^2=0.0\%$, $P=0.02$) (**Table III**).

33 34 35 *Association between cigarette smoking of gender and NPC*

36
37 Seven studies addressed the association between cigarette smoking and NPC risk
38 by gender, including five in males and two in females. Compared with never smokers,
39 increased risk for male smokers was noted (OR, 1.36; 95% CI, 1.15-1.60). However,
40 an insignificant association (OR, 1.58; 95% CI, 0.99-2.53) was observed for female

2
3 smokers (**Table III**).

4
5 *Sensitivity analysis and publication bias*

6
7 Sensitivity analysis revealed that Ji 2011 study [42] was the source of statistical
8 heterogeneity in the pooled analysis for ever smokers. When this outlier study was
9 removed, between-study heterogeneity dropped strikingly to 27.3% in the remaining
10 studies, whereas the odds ratios (OR, 1.47; 95% CI, 1.31-1.66) changed moderately
11 but remained significant. As for case-control studies, the OR changed from 1.61 (95%
12 CI: 1.36-1.91) to 1.52 (95% CI: 1.35-1.72) with heterogeneity fallen from 65.8% to
13 23.5% (**Figure 5**). The findings were further verified in the intermediated incidence
14 rate group (OR, 1.49, 95% CI, 1.21-1.82; heterogeneity: $I^2=49.6\%$, $P=0.04$) and in the
15 adjusted group (OR, 1.45; 95% CI, 1.25-1.69; heterogeneity: $I^2=41.8\%$, $P=0.05$) (data
16 not shown). However, the heterogeneity reduced partly when the study of Turkoz
17 2001 was removed (OR, 1.50; 95% CI, 1.28-1.76; heterogeneity: $I^2=62.4\%$, $P<0.01$)
18 (data not shown).
19

20
21 Publication bias was evaluated by Egger's test and Trim-and-Fill method. Except
22 for subgroup analyses with ever smokers and heavy smokers, no prominently
23 significant publication bias (with $P>0.05$ in Egger's test) was observed in our
24 meta-analysis. After adjusted for publication bias, the risk of NPC remained stable
25 with an OR of 1.56 (95% CI, 1.32-1.84) for ever smokers, but changed slightly (OR,
26 1.80, 95% CI, 1.37-2.36) for heavy smokers (**Table III**).
27

28
29 **Discussion**

30
31 The results from this meta-analysis, based on seventeen case-control studies and
32 four cohort studies, supported that there was moderate association between cigarette
33 smoking and nasopharyngeal carcinoma risk, which was consistent with the result of
34 previous meta-analysis [13].
35

36
37 *Interpretation*

38
39 The pooled risk estimate for cohort studies comparing ever smokers to never
40 smokers was not statistically significant. When conducted similar stratified analyses
41 for current smokers and former smokers, we found that current smoking was
42 significantly related to the risk of NPC while former smoking had an insignificant

60

association with NPC risk. Considering the findings of stratified analyses, it might be the result from former smoking that contributed to the discrepancy between pooled analysis for cohort studies and overall analysis. In addition, this meta-analysis demonstrated relatively high heterogeneity both for the overall analysis and subgroup analyses. When the Ji 2011 study [44] was removed from the synthetic analysis, heterogeneity was strikingly reduced in stratified analysis by study design and regions with different NPC incidence rate. Furthermore, the meta-regression analyses indicated that heterogeneity did not prominently result from publication year, study design, regions of different incident rate and quality of studies. To our knowledge, multiple lines of epidemiological studies had found that the development of NPC could be influenced by varieties of etiologies including Epstein-Barr virus (EBV), genetic components and other environmental factors, like preserved food, socioeconomic status, occupation, so on and so forth [6, 47-50]. Therefore, it might be its inappropriate subjects that contributed to selection bias which resulted in the high heterogeneity in the Ji 2011 study, though it had a large sample size with risk estimates adjusted by age, gender, alcohol intake and family history.

One large cohort study [10], conducted in high-incidence region and comprised the majority of undifferentiated NPC (nearly 90% cases), did not reported statistically increased risk of NPC among current smokers compared with never smokers. The difference in the effect of current smoking on NPC risk may be due to its histological type of NPC because undifferentiated carcinoma in high-risk areas seemed more strongly related to Epstein-Barr virus infection other than cigarette smoking [48]. Meanwhile, some case-control studies with small sample size of current smokers also had null results [7-9, 38, 39], of which two studies pointed out that significantly higher risk only existed for smokers with considerable levels of cigarette smoking (>20 cigarettes/day or >30 pack-years) [38, 39]. Nonetheless, the result of our integrated analysis for current smokers versus never smokers was generally consistent with that of the previous meta-analyses [13].

For former smokers, the less consistent risk estimates might result from small number of studies with adequate sample size. The estimates for former smokers in

1
2
3 eight studies [7-10, 26, 39, 41, 46] presented null association on NPC risk which was
4 parallel to the results of stratified analysis by study design, and only two studies [23,
5 38] demonstrated statistically positive results. The discrepancies in the effects of
6 former cigarette smoking on NPC risk might arise from the following aspects: the
7 group of former smokers may have included people who had quit for a long time, and
8 thus their risk might diminish or even reach the level of never smokers; the minimum
9 period of time since quitting smoking in former smokers varied by study, which could
10 result in judgement bias on the interviewed subjects in some studies.
11
12

13
14
15
16
17
18 This meta-analysis revealed that there was a clear dose-response relationship
19 between cigarette smoking and the risk of NPC. That is, the more cigarette smoking
20 (intensity of cigarettes smoked per day and the amount of pack-years), the higher risk
21 for the development of NPC. Note that similar results have been widely observed for
22 pancreatic cancer, liver cancer, renal carcinoma and gallbladder disease [51-54]. The
23 exact explanation of this dose-dependent effect remains vague, it could be
24 hypothesized that the more cigarette smoking, the greater impact on the epithelial
25 cells of nasopharynx. Therefore, the risk of NPC would be higher in those who
26 smoked more cigarettes. The actual mechanism about the relationship of the amount
27 of smoking and NPC risk had been searched by molecular studies [55, 56], which
28 pointed out that smoking is a factor for tumor growth and acts as a mutagen and DNA
29 damaging agent that drives tumor initiation in normal epithelial cells of nasopharynx.

31
32
33
34
35
36
37
38
39
40

41 In this analysis, a statistically significant effect of smoking on NPC risk was
42 observed in males but not in females. The gender difference in response to smoking
43 might be related to interaction between protective endogenous or exogenous estrogens
44 among women compared with men [57], and could also be explained by maturity of
45 smoking trends among males and but not among females. Men might exposure to
46 smoking for a longer duration as compared to women (34% of the male vs. 11% of the
47 female had started smoking before the age of 15 years) [58]. However, the result of
48 female ever smokers might not be adequately stable because only two studies reported
49 the association between cigarette smoking and the risk of NPC for females [35, 41].

60

risk they developed NPC. Our results showed that the pooled ORs were 1.78 (95% CI, 1.41-2.25) for smokers in early group and 1.28 (95% CI, 1.00-1.64) in later group, respectively. Interestingly, the findings of previous meta-analysis appeared totally opposite with ORs of 1.17 (95% CI, 0.78-1.75) for early group and 1.58 (95% CI, 1.10-2.26) for later group [13]. Like many other cancers, NPC may take decades to develop from premalignant cells to detectable solid tumor. Thus, the exposure to carcinogenic agents early in life could have substantial impacts on the development of NPC [6, 59]. Moreover, the incidence of NPC peaks at age of 50-59 years in high-risk regions, while in western countries, the incidence of NPC peaks somewhat later (≥ 65 -year-olds) [59]. As a result, the number of NPC patients in terms of age distribution could considerably vary in our eligible studies that were conducted in different countries.

When stratified by histological type of NPC, the pooled analysis presented a higher risk of differentiated NPC than that of undifferentiated NPC, and the later had an insignificant risk estimate. This difference might be owing to fewer studies included in the pooled analysis for undifferentiated NPC because we excluded those ineligible studies either for no report of the association between cigarette smoking and NPC risk [16] or for overlapped data [60]. It might avoid incorrect estimation of smoking effects on NPC risk. Moreover, we found that the risk estimates adversely associated with the NPC incidence rate. For example, the pooled OR for high incidence rate areas to low incidence rate areas ranged from 1.27 to 1.68. This might suggest there are substantial heterogeneity between NPC risk and smoking by histological types and geographic variations. Undifferentiated carcinoma of the nasopharynx is the predominant type in high-risk areas, and it is consistently associated with EBV infection, which may increase the carcinogenic effect of cigarette smoking [48].

Generalizability

The magnitude of association between cigarette smoking and the NPC risk was not as big as those for other smoking-related cancers like lung cancer and gastrointestinal malignancies [4]. However, NPC was quite epidemic in southeastern

1
2
3 Asia especially in cities in southern China, and China was one of the largest tobacco
4 producing and consuming countries in the world [61]. Besides, we found current
5 smokers are more related to the development of NPC with a higher risk estimate as
6 compared to former smokers. These emphasized the importance and urgency of
7 efforts to initiate the control of cigarette smoking to improve public health. Any
8 efficient tobacco control programs would be helpful to reduce morbidity and mortality
9 of smoking-related cancers worldwide.

16 **Limitations**

17
18 The results of this meta-analysis should be explicated in the context of several
19 limitations. For example, the design of included studies varied in source of subjects
20 recruited, standardization for categories of cigarette smoking, ambiguous definition of
21 tobacco products and adjusted factors. Additionally, our meta-analysis was a mix of
22 retrospective studies and prospective studies, and was lack of individual participant
23 data for adjustment of potential confounders. Generally, Epstein-Barr virus infection
24 was thought to be highly related to NPC risk [62]. However, a 22-year follow-up
25 study carried out by Hsu et al. revealed that Epstein-Barr virus was less likely to
26 modify the estimate for smoking associated with NPC risk [43]. And the links of other
27 risk factors like dietary and social practices were often inconsistent between studies
28 [62]. Moreover, the risk estimates of NPC resembled both in the group with adjusted
29 odds ratio and in the group with unadjusted odds ratio in our meta-analysis.

41 **Conclusions**

42
43 This meta-analysis demonstrated that cigarette smoking associated with a modest,
44 but statistically significant increased risk of NPC. Yet, further prospective studies are
45 needed to elucidate the NPC risk in terms of gender, histological type, and for former
46 smokers and smoking onset age.

Table I. General characteristics of case-control studies used for meta-analysis

Study	Region	Period	Incidence rate	Cases/Controls	Male/Female	Age range (years old)	Quality score	Source of controls	Matching factors	Adjusting factors
Mabuchi et al (34)	the US	—	Low	39/39	—	—	7	Hospital-based	Age, sex, race, Education, occupation, marital status	—
Yu et al (37)	Guangzhou	1983-1985	High	306/306	209/97	Under 45	7	Population-based	Age, sex, residence, education	Birth place, marital status, dietary risk
Nam et al (35)	the US	1983-1986	Low	204/408	141/63	Under 65	5	Hospital-based	Age, sex	By multiple logistic regression analysis
Sriamporn et al (36)	Thailand	1987-1990	Moderate	120/120	81/39	mean 47.2	6	Hospital-based	Age, sex	Age, sex, education, residence, occupation, consumption of salted fish and alcohol
Zhu et al (38)	the US	1984-1988	Low	113/1910	male	—	8	Population-based	—	Birth, education, background, medical history, occupation, alcohol intake
Vaughan et al (39)	the US	1987-1993	Low	231/244	154/77	mean 55.2	9	Population-based	Age, sex, region	Age, sex, alcohol use, education
Cheng et al (7)	Taiwan	1991-1994	Moderate	375/327	260/115	mean 46 (15-74)	7	Population-based	Age, sex, residence, education, marital status	Age, sex, race, education, family history of NPC, drinking status
Chelleng et al (40)	India	1996-1997	Moderate	47/94	34/13	mean 43.7	6	Population-based	Age, sex, ethnicity	—
Yuan et al (41)	Shanghai	1987-1991	Moderate	935/1032	668/267	mean 50	8	Population-based	Age, sex, residence	Age, gender, education, intake frequencies of preserved foods, occupational exposure history of chronic ear and nose condition, family history of NPC

Table I. Continued

Study	Region	Period	Incidence rate	Cases/ Controls	Male/ Female	Age range (years old)	Quality score	Source of controls	Matching factors	Adjusting factors
Zou et al (51)	Yangjiang	1987-1995	High	97/192	83/14	mean 52.6 (30-82)	7	Population-based	Age, sex, occupation	—
Feng et al (42)	North Africa	2002-2005	Moderate	440/409	male	—	7	Hospital-based	Age, sex, ethnicity, center, childhood household type	Age, socioeconomic status, dietary risk factors
Ji et al (44)	Wuhan	1991-2009	Moderate	1044/1095	755/289	—	5	—	Age, sex, ethnicity	Age, gender, cigarette, alcohol intake, family history
Polesel et al (9)	Italy	1992-2008	Low	150/450	119/31	median 52 (18-76)	6	Hospital-based	Age, sex, residence	Age, sex, place of residence, education, alcohol intake
Turkoz et al (45)	Turkey	—	Moderate	183/183	122/61	mean 44.9 (18-75)	6	Hospital-based	Age, sex	Age, sex
Fachiroh et al (23)	Thailand	2005-2010	Moderate	681/1078	504/177	mean 49.8	6	Hospital-based	Age, sex, residence	Age group, sex, center, education, alcohol drinking
Lye et al (25)	Malaysia	2007	Moderate	356/356	276/80	mean 53.2	6	Hospital-based	Age, sex, ethnicity	Age, sex, ethnicity, salted fish and alcohol intake
Xie et al (26)	Hong Kong	2010-2012	High	352/410	253/99	mean 51.6	8	Population-based	Age, sex, ethnicity, residence district	Age, sex, education, house type, family history of NPC, environmental tobacco smoke exposure, dietary risk, occupational exposure and cooking experience

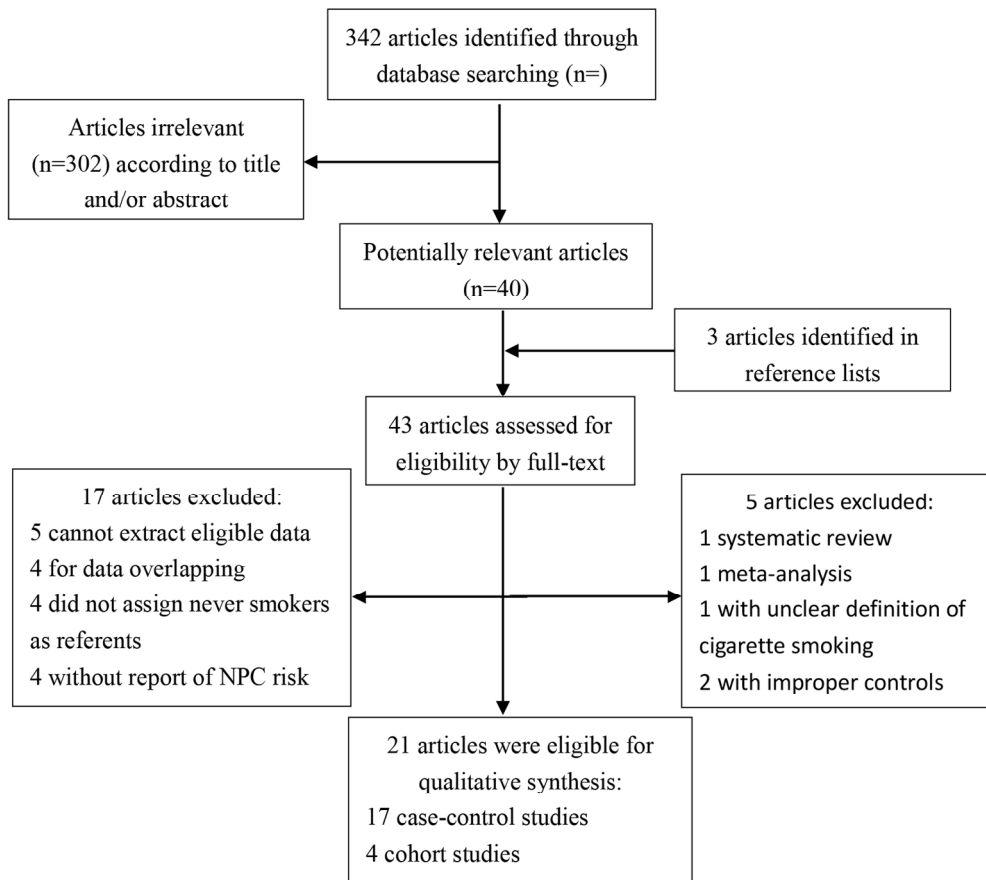

Table II. General characteristics of cohort studies used for meta-analysis

Study	Region	Period	Incidence rate	Cohort size	No. of cases	Years of follow-up	End-point	Quality score	Source of cohort	Adjusting factors
Chow et al (46)	the US	1954-1980	Low	248046	48	26	Mortality	6	Veterans	Age, calendar year
Friborg et al (10)	Singapore	1993-2005	High	61320	173	12	Morbidity	9	Population-based	Age, sex, dialect group, year of interview, education
Hsu et al (43)	Taiwan	1984-2006	Moderate	9622	32	mean 18.1	Incidence	9	Population-based	Age, two anti-EBV viral serum-markers
Lin et al (24)	Guangzhou	1988-1999	High	101823	34	mean 7.3	Incidence	8	Factory workers and drivers	Age, sex, education, drinking status, occupation

Table III. Subgroup analysis on pooled ORs for the association between cigarette smoking and nasopharyngeal carcinoma.

Subgroup	No. of Studies	Effect estimate (95% CI)	Heterogeneity I^2, P	Egger's Test P value	Adjusted for Publication Bias
<i>Smoking status</i>					
Ever smokers	19	1.56(1.32-1.83)	66.8%, <.01	0.29	1.56(1.32-1.84)
Current smokers	11	1.59 (1.35-1.89)	32.5%, .14	0.10	
Former smokers	10	1.36 (1.15-1.61)	2.3%, .42	0.97	
<i>Design</i>					
Case-control					
Current smokers	8	1.67(1.06-2.61)	22.6%, .25	0.58	
Former smokers	8	1.45(1.21-1.73)	0.0%, .70	0.98	
Cohort					
Current smokers	3	2.19(1.02-4.72)	65%, .06	0.16	
Former smokers	2	0.87(0.54-1.41)	0.0%, .37	—	
<i>Pack-years</i>					
<30	7	1.34 (1.13-1.58)	0.0%, .73	0.54	
≥30	6	2.03 (1.57-2.61)	0.0%, .45	<0.01	1.80(1.37-2.36)
<i>Age at onset of smoking</i>					
<18y	5	1.78 (1.41-2.25)	0.0%, .94	0.46	
≥18y	5	1.28 (1.00-1.64)	0.0%, .86	0.93	
<i>Incidence rate</i>					
Low	5	1.68 (1.36-2.07)	0.0%, .84	0.64	
Intermediate	10	1.59 (1.21-2.09)	78.8%, <.01	0.29	
High	4	1.27 (1.05-1.53)	0.0%, .52	0.63	
<i>Gender</i>					
Male	5	1.36 (1.15-1.60)	0.0%, .68	0.48	
Female	2	1.58 (0.99-2.53)	0.0%, .64	—	
<i>Histological type</i>					
Differentiated	5	2.34 (1.77-3.09)	0.0%, .72	0.64	
Undifferentiated	4	1.15 (0.90-1.46)	0.0%, .02	0.28	
<i>Adjustment</i>					
Adjusted	13	1.55 (1.26-1.91)	75.4%, <.01	0.33	
Unadjusted	6	1.57 (1.27-1.93)	0.0%, .68	0.93

STROBE Statement—checklist of items that should be included in reports of observational studies

	Item No	Recommendation
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract Page 1 (b) Provide in the abstract an informative and balanced summary of what was done and what was found Page 2
Introduction		
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported: Page 4
Objectives	3	State specific objectives, including any prespecified hypotheses Page 4-5
Methods		
Study design	4	Present key elements of study design early in the paper Page 1-2
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection Page 5-7
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants (b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case Page 6 and Table 1&2
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable
Data sources/measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group Page 5
Bias	9	Describe any efforts to address potential sources of bias Page 3
Study size	10	Explain how the study size was arrived at Page 2 or 7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why Page 5-6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding (b) Describe any methods used to examine subgroups and interactions (c) Explain how missing data were addressed (d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy (e) Describe any sensitivity analyses Page 6-7

Results

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed (b) Give reasons for non-participation at each stage (c) Consider use of a flow diagram Page 7-8
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders (b) Indicate number of participants with missing data for each variable of interest (c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount) Page 8
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time <i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure <i>Cross-sectional study</i> —Report numbers of outcome events or summary measures Page 7-8
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included (b) Report category boundaries when continuous variables were categorized (c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period Page 8-11
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses Page 10-11

Discussion

Key results	18	Summarise key results with reference to study objectives Page 11-14
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias Page 15
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence Page 11-14
Generalisability	21	Discuss the generalisability (external validity) of the study results Page 14-15

Other information

Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based Page 16
---------	----	--

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.

MOOSE Checklist for Meta-analyses of Observational Studies

Item No	Recommendation	Reported on Page No
Reporting of background should include		
1	Problem definition	4
2	Hypothesis statement	5
3	Description of study outcome(s)	5
4	Type of exposure or intervention used	4
5	Type of study designs used	4
6	Study population	8
Reporting of search strategy should include		
7	Qualifications of searchers (eg, librarians and investigators)	None
8	Search strategy, including time period included in the synthesis and key words	5
9	Effort to include all available studies, including contact with authors	5
10	Databases and registries searched	5
11	Search software used, name and version, including special features used (eg, explosion)	5
12	Use of hand searching (eg, reference lists of obtained articles)	5
13	List of citations located and those excluded, including justification	7
14	Method of addressing articles published in languages other than English	5
15	Method of handling abstracts and unpublished studies	7
16	Description of any contact with authors	None
Reporting of methods should include		
17	Description of relevance or appropriateness of studies assembled for assessing the hypothesis to be tested	5
18	Rationale for the selection and coding of data (eg, sound clinical principles or convenience)	5
19	Documentation of how data were classified and coded (eg, multiple raters, blinding and interrater reliability)	6
20	Assessment of confounding (eg, comparability of cases and controls in studies where appropriate)	6
21	Assessment of study quality, including blinding of quality assessors, stratification or regression on possible predictors of study results	6
22	Assessment of heterogeneity	7
23	Description of statistical methods (eg, complete description of fixed or random effects models, justification of whether the chosen models account for predictors of study results, dose-response models, or cumulative meta-analysis) in sufficient detail to be replicated	6
24	Provision of appropriate tables and graphics	7
Reporting of results should include		
25	Graphic summarizing individual study estimates and overall estimate	8
26	Table giving descriptive information for each study included	20
27	Results of sensitivity testing (eg, subgroup analysis)	9
28	Indication of statistical uncertainty of findings	11

Item No	Recommendation	Reported on Page No
Reporting of discussion should include		
29	Quantitative assessment of bias (eg, publication bias)	12, 14
30	Justification for exclusion (eg, exclusion of non-English language citations)	None
31	Assessment of quality of included studies	12
Reporting of conclusions should include		
32	Consideration of alternative explanations for observed results	15
33	Generalization of the conclusions (ie, appropriate for the data presented and within the domain of the literature review)	14
34	Guidelines for future research	15
35	Disclosure of funding source	16
