Supplemental Material

Supplementary figures

Supplementary fig. 1. The prevalence of metabolic consequences in obese children (N = 82) 27 patients of 82 obese children had either hypertension (according to 24-hour monitoring), carbohydrate metabolism disorder (impaired glucose tolerance) and/or dyslipidemia (elevated cholesterol level). One patient had all three of the above mentioned comorbidities and also presented elevated uric acid level. According to our results hypertension and dyslipidemia individually was present in 18.29–18.29 % and carbohydrate metabolism disorder was present in 13.41% of the cases. 9 of 55 the patients without hypertension, impaired glucose tolerance and dyslipidemia presented isolated hyperuricemia (data not shown). 46 patients did not present any signs of comorbidities.
