90

91

113 Supplementary Information

114 Discrepancies in mutational data between CCLE and GDSC

115 We investigated a set of 64 genes for the presence of mutations in both the CCLE and GDSC
116 datasets. We investigated the consistency of mutation patterns. Thirteen genes were reported
117 to have no mutations in GDSC, in any of the 471 cell lines studied (AKT2, CCND1, CCND2,
118 CCND3, CDK4, CDK6, EP300, FGFR2, MDM2, MLLT3, MYCL1, MYCN and
119 SMARCB1). We focused on the remaining 51 genes. The most frequently mutated gene was
120 TP53, with a frequency over 60%, mutation frequencies remaining below 20% for the other
121 genes (Supplementary Fig. 6A). A previous study reported high levels of agreement
122 concerning the reported presence of mutations in identical cell lines¹. However, for cell lines
123 displaying mutations of at least one of these genes, the mean proportion of cell lines with
124 mutations of the same genes was about 20% (Supplementary Fig. 6C) and the mean
125 proportion of cell lines displaying identical mutations within the genes was 44%
126 (Supplementary Fig. 6D). Only for eight genes (TP53, KRAS, NRAS, APC, PIK3CA, BRAF,
127 PTEN and RB1) did at least 5% of identical cell lines display mutations in both datasets
128 (Supplementary Fig. 6B). Furthermore, the proportion of identical cell lines mutated was
129 64%, and the mutations observed were identical in 84% of cases. By contrast, 12% of
130 identical cell lines had mutations for the remaining genes, with 36% of the mutations
131 observed identical (Supplementary Fig. 6C-D).

132 Drug screening data

133 The large-scale drug screening programs of the Broad and Sanger Institutes have provided to
134 the scientific community an unprecedented wealth of publicly available data. Molecular data
135 have been systematically collected for each cell line, but far less information is available for

136 drug screening. Considering the 471 cell lines common to CCLE and GDSC, only 47% of the
137 cell lines from CCLE and 90% of those from GDSC have been tested for at least one drug
138 (Supplementary Fig. 7). In CCLE and GDSC, 28% and 22% of the cell lines, respectively,
139 were tested for all compounds. Moreover, in many cases (25% in CCLE and 45% in GDSC) it
140 was not possible to extract the IC₅₀ from the dose-response curve. In these cases, the IC₅₀ was
141 set to the maximum concentration used for screening in the CCLE study, whereas a
142 mathematical extrapolation was applied in the GDSC study. In order to overcome these
143 issues, both study also report the AUC (area under the dose response curve) that can always
144 be calculated.

145

146 Comparison between CCLE and GDSC based on AUC

147 To evaluate the relevance of our method to the variation of drug sensitivity metric, we looked
148 at the area under the dose response curve (AUC). We evaluate the robustness of our cell line
149 classification with the 15 drugs shared between CCLE and GDSC.

150

151 We first evaluated whether our clustering was more discriminant than the tissue of origin of
152 the cell lines, in terms of drug response. We calculated a pseudo *F*-statistic using the AUC
153 values for each of the 15 drugs common to CCLE and GDSC. Ten out of fifteen drugs had a
154 higher ratio in CCLE and GDSC for our clustering than for clustering based on tissue source
155 (Supplementary Fig. 4). This trend was confirmed by a *t*-test comparing the pseudo *F* values
156 for our clustering with those for ‘tissue partitioning’ (CCLE *t.test p-value* = 0.011, GDSC
157 *t.test p-value*=0.043).

158

159 We then performed the same analyses as those performed with the IC₅₀, to identify
160 association between cell line clusters and drug response but based on the AUC. Four out of

161 the seven cell lines clusters-drugs associations were robustly found using the IC₅₀ and the
162 AUC (Supplementary Table 7 and Fig. 8): ADG cluster being sensitive to erlotinib, SKCM
163 being sensitive to the Raf kinase B inhibitor PLX4720 and the MEK inhibitor AZD6244
164 whereas the latter is not active in BRCA cell line cluster. In addition, SKCM cluster appears
165 resistant to crizotinib (ALK inhibitor) and AZD0530 (Src and Abl inhibitor) that is
166 concordant with the wild-type mutational status of SCKM cells for ALK, Abl1/2 and Src².
167 Lapatinib appears inefficient in HAL cluster that is consistent as no EGFR or ERBB2
168 mutation have been reported in HAL cell lines in both CCLE and GDSC.

169 Many cell lines never achieved 50% inhibition for many drugs. In this case, data have been
170 either truncated by the maximum dose tested (as in CCLE), either they have been extrapolated
171 (as in GDSC) (Supplementary Figure 5). On the contrary the AUC can always be calculated.
172 These variabilities can explain the variation of results. However more than half of the cell
173 lines clusters-drug associations were found using both IC50 and AUC.

174

175 Comparison between CCLE, GDSC and GSK

176 We explored the relevance of our classification with two outside datasets. For this, we kept
177 our robust clustering of cell lines define with the CCLE and GDSC. For each dataset and each
178 drug separately, we investigated whether the mean drug sensitivity measure available of a
179 given cell line cluster differed significantly from those for the other cell line clusters (see
180 Materials and Methods). We then investigate if significant cell line clusters-drug associations
181 can be found in these different datasets.

182 First we consider the third dataset used by Haibe-Kains et al¹, the GlaxoSmithKline cell line
183 collection (GSK)³. This panel is composed of 319 cell lines that have been screened on 19
184 drugs. Only lapatinib and paclitaxel have been tested by GSK among the 15 drugs shared
185 between CCLE and GDSC. A set of 194 cell lines was common to the three studies. However

186 the actual number of cell lines for which we have a sensitivity measure for lapatinib and
187 paclitaxel is smaller especially in GDSC. Supplementary Table 4 shows the number of cell
188 lines with a sensitivity measure for each drug in each dataset among the 194 cell lines shared
189 between CCLE, GDSC and GSK. Only 70 cell lines have a sensitivity measure for paclitaxel
190 and lapatinib in GDSC. Moreover, the number of cluster with less than 3 cell lines goes up to
191 4 for paclitaxel and 5 for lapatinib. Given the too small number of cell lines available, we
192 therefore compared only the results between CCLE and GSK. Comparisons were based on
193 IC₅₀, the unique measure available in GSK. Two associations were found in both CCLE and
194 GSK suggesting that lapatinib is inactive in SKCM and in Mixed 1 clusters (Supplementary
195 Table 8, Supplementary Fig. 9 and 10). Prickett et al⁴ found some evidence that lapatinib may
196 be more active in melanoma cell lines with ErbB4 mutations than wild-type melanoma cells.
197 However, no ErbB4 mutations have been called in melanoma cells from cluster SKCM².

198

199 Comparison between CCLE, GDSC and gCSI

200 Since the set of common cell lines and drugs was small between CCLE, GDSC and GSK
201 (Supplementary Table 4), we repeated the analysis with the panel introduced by the
202 Genentech Cell Line Screening Initiative (gCSI)⁵. Data were recovered from the R package
203 *compareDrugScreens*. A panel of 244 unique cell lines and 5 drugs overlap between CCLE,
204 GDSC and gCSI. Once again the overlap of cell lines between GDSC and gCSI is relatively
205 small (Supplementary Table 4). Drug sensitivity measure was available for less than 3 cell
206 lines in 4 clusters for erlotinib and lapatinib; in 3 cell line clusters for crizotinib and
207 paclitaxel. For these reasons, we focused only on PD0325901 when comparing GDSC and
208 gCSI. Two measures of sensitivity are available in *compareDrugScreens*. In addition to the
209 classical IC₅₀, they introduced the mean viability statistic that is the arithmetic average of the
210 fitted viabilities at each tested dose. This metric is closely related to the AUC. We used the

211 mean viability to evaluate the robustness of our cell line classification to the drug sensitivity
212 metric variation.

213 Height associations were found significant in both CCLE and gCSI using the IC₅₀
214 (Supplementary Table 9, Supplementary Fig. 11 and 12). Among them three were also found
215 when comparing CCLE to GDSC: ADG cluster sensitive to erlotinib and lapatinib;
216 PD0325901 actives in SKCM. In addition, the resistance of Mixed 1 cluster to lapatinib found
217 when comparing CCLE to GSK appeared once again significant here. Additional associations
218 were found specifically. Erlotinib were inactive to treat cells from Mixed 1, GLSR and
219 SKCM. BCRA cluster was found resistant to PD0325901. Regarding the comparison with
220 GDSC, a strong trend could be observed between SKCM and PD0325901 (gCSI Effect =
221 0.39, adjusted p-value =3.05E-10, GDSC Effect = 0.13, adjusted p-value =0.058).

222 Considering the mean viability statistic (Supplementary Table 10, Supplementary Fig. 13 and
223 14), 2 associations among those identified when comparing CCLE to GDSC were found
224 again: ADG cluster sensitive to erlotinib and SKCM sensitive to PD0325901. In addition, 8
225 more clusters were found resistant to erlotinib: SCLC, Mixed 1, HAL, GLSR and SKCM.
226 These findings were supported by several phase II studies reporting the inactivity of erlotinib
227 in patients with gliomas^{6,7} and melanomas⁸ as well as the lack of EGFR mutation in small-cell
228 lung cancers⁹. BRCA appeared resistant to the MEK inhibitor PD0325901. It has been shown
229 that PD0325901 is more active in basal-like breast cancer lines than in luminal and Her2+
230 lines¹⁰. Indeed, only 3 out of the 10 breast cancer cell lines from BRCA cluster that have been
231 tested for PD0325901 are TNBC. For GDSC, similar results than those found with the IC₅₀
232 were found regarding the sensitivity of SKCM to PD0325901.

233

234

235

236 Distinct drug profiles were associated with the various cell line clusters
237 The GI cell line cluster was sensitive to drugs targeting the ERK signaling pathway (MEK1/2,
238 Hsp90): 17AAG, AZD6244, PD0325901 (Supplementary Fig. 15). The targeting of this
239 pathway was also found to be effective against the cell lines of the ADG cluster, but only for
240 drugs targeting EGFR and ERBB2. Furthermore, these cell lines seems to be particularly
241 sensitive to drugs acting on the cytoskeleton. SKCM cell lines were sensitive to drugs
242 inhibiting the ERK signaling pathway, regardless of the protein from this pathway targeted
243 (BRAF, MEK1/2, FLT3, JAK2, NTRK1, RET). Hematopoietic cells were sensitive to
244 molecules targeting apoptosis, the cell cycle and the cytoskeleton, and to inhibitors of PARP,
245 topoisomerase I and the ERK signaling pathway. AKT-INHIBITOR-VIII and MK-2206, two
246 AKT1/1 inhibitors, were found efficient on BRCA cells. Indeed, the PI3K/mTOR pathway is
247 commonly deregulated in breast cancer¹¹. The 15 drugs to which cell lines of the GLSR were
248 sensitive included seven PIK3/mTor inhibitors. Kinase inhibitors and chemotherapy agents
249 targeting the mitotic spindle were also identified as potentially effective drugs against GLSR
250 cells. Chemotherapy agents (gemcitabine, bleomycin, vinblastine) were the most active drugs
251 for killing cells from the Mixed 1 cell line cluster. The other two heterogeneous clusters were
252 each sensitive to only one drug: midostaurin-a PI3K/mTOR inhibitor for Mixed 2, and
253 vorinostat, a HDAC inhibitor, for Mixed 3. Finally, the cell lines of the EDOT cluster were
254 sensitive only to the chemotherapy agent doxorubicin.

255
256 Resistance profiles were identified for 163 associations between cell line clusters and drugs.
257 More than 30% of these associations involved inhibitors of the ERK and PI3K/mTOR
258 signaling pathways. All but one of the clusters appeared to be resistant to at least three drugs
259 targeting this pathway. The exception was the Mixed 2 cluster, which was resistant only to the
260 MEK1/2 inhibitor AZD6244). The cell lines of the various clusters were otherwise resistant to

261 a broad range of diverse drugs. The cell lines of the SCLC cluster were resistant to the largest
262 number of molecules (22% of all the drugs tested), including, drugs targeting the apoptosis,
263 NOTCH or Wnt signaling pathways. Drugs targeting the cytoskeleton, mitosis and replication
264 appeared to be the least effective for killing the cell lines of the GI cluster. By contrast, the
265 cell lines of the ADG cluster were found to be resistant to a drug targeting the cytoskeleton, a
266 drug targeting the Wnt pathway and a drug targeting G-protein–coupled receptors.
267 Topoisomerase I inhibitors, such as topotecan and camptothecin, were found ineffective to
268 kill BRCA cells. Surprisingly, gemcitabine and methotrexate were also found to be inefficient
269 against these cells, despite their widespread use in clinical practice. Mixed clusters presented
270 only a small number of resistant associations.

92 **Supplementary data – 1 and 2**

93 Summary of each cell line cluster with information regarding tissue composition, molecular
94 profile and drug profile in respectively CCLE and GDSC.

95 The first block shows the cell lines belonging to the given cluster.

96 The second block shows tissue composition.

97 First window: proportion of lines for the cluster originating from a given tissue.

98 Second window: proportion of the lines from a given tissue belonging to the cluster.

99 Third window: Molecular profile of the cluster.

100 Mutation type of each cell line. Genes and cell lines are sorted according to the number of
101 events. The expression profile of the cluster relative to all the other cell lines for the defined
102 gene clusters is shown. The proportion of epithelial or mesenchymal cells, according to the
103 signature defined by Taub *et al.*

104 The last window illustrates the drug profile associated with the cluster. A volcano plot
105 representation of *t*-test results showing the magnitude (effect; *x*-axis) and significance (-log10
106 (*p*-value); *y*-axis) of all drug-cluster associations in the dataset. Each circle represents a single
107 drug-cluster interaction and its size is proportional to the number of cell lines screened. The
108 horizontal dashed line indicates the threshold of statistical significance (-log10(0.05)). Barplot
109 representation of the *t*-test results showing the proportion of drug types significantly
110 associated with the cluster. List of drugs associated with the cluster (FDR < 0.05) and their
111 phenotype.
