**Supplementary Figure 1: SCLC displays increased mRNA expression levels of numerous genes involved in different DNA repair pathways, compared to SqCC and ADC.**

Displayed are the expression levels of different genes involved in (A) mismatch repair (*MSH2*, *MSH6*), (B) base excision repair (*PARP1*, *PARP2*, *MUTYH*, *REQL4*), (C) homology-directed repair (*BRCA1*, *BRCA2*, *RAD51*, *RAD51AP1*, *RAD51C*, *RAD54B*, *RAD54L*, *BLM*, *TOPBP1*) and (D) interstrand crosslink repair (*FANCA*, *FANCB*, *FANCC*, *FANCG*, *FANCI*, *FANCM*). Expression levels are displayed as a box plots. Whiskers indicate the 10-90 percentile. \*\*\*<0.0001 (Mann Whitney test). The histological annotation of the lung tumor samples is provided in the color panel (top right).

**A****B**

**Supplementary Figure 2: Alternative ATR- and CHK1 inhibitors display similar cytotoxicity, as VE-822 and PF-477736 in SCLC cell lines.**

(A-B) Intracellular ATP was measured to assess cell viability. Average values of three independent experiments are shown. RP cell lines were more sensitive to ATR inhibition (AZD-6738) and CHK1 inhibition (AZD-7762), than KP cell lines.

**Supplementary Figure 3: Genotoxic damage in murine SCLC cell lines following ATR- and CHK1 inhibition is independent of growth kinetics.**

(A-C) RP 2 and 5 cell lines were stained with an antibody detecting  $\gamma$ H2AX and a DAPI counterstain. VE-822 and PF-477736 induced genotoxic damage in RP2 and RP5 cells.

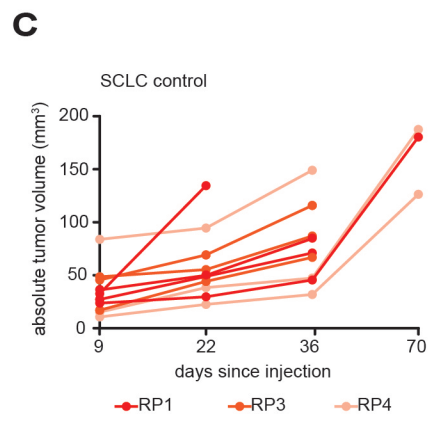

(A) Representative immunofluorescence images are shown for RP 2 and 5 cell lines following a 24-hour exposure to the indicated treatments.

(B-C) The percentage of  $\gamma$ H2AX-positive cells was quantified. VE-822 (0.75 $\mu$ M) and PF-477736 (1.0 $\mu$ M) induced DNA damage after a drug exposure of 12, 24 and 48 hours in both RP cell lines.

(D-E) Immunoblot was executed on RP 2 and 5 cell lines after VE-822 (0.75 $\mu$ M) or PF-477736 (1 $\mu$ M) treatment for 48 hours. Vehicle-treated cells served as a control.  $\beta$ -actin was used as a loading control.

(D) Representative immunoblot images are shown for RP 2 and 5 cells.

(E) The intensity of enhanced chemiluminescence signal was quantified using densitometry. RP 5 cells displayed a stronger  $\gamma$ H2AX signal, than RP 2 cells following VE-822 and PF-477736 treatment.

**Supplementary Figure 4: ATR- and CHK1 inhibition is therapeutically effective in SCLC tumors, *in vivo*.**

(A) Representative images of Ki67 staining from untreated mice bearing SCLC or NSCLC tumors from the allograft model. Scale bar 25 $\mu$ m.

(B) Absolute tumor volume is displayed in mm<sup>3</sup> for all NSCLC-bearing mice in the vehicle-treated cohort (n=7) and in the VE-822- (n=6) and PF-477736-treated (n=6) cohort. Three animals in the vehicle-treated cohort and one animal in the VE-822-treated cohort died before completion of cycle 4.

(C) Absolute tumor volume is displayed in mm<sup>3</sup> for all SCLC bearing mice in the vehicle-treated cohort (n=10) and in the VE-822- (n=12) and PF-477736-treated (n=12) cohort. One animal in the vehicle-treated cohort died before completion of cycle 4. The post treatment phase until day 70 was survived by 15 animals (vehicle-treated n=3; VE-822-treated n=7, PF-477736-treated n=5).

**Supplementary Figure 5: VE-822 and PF-477736 induce substantially more viability reduction in human SCLC cells, compared to human NSCLC cells.**

(A-D) Intracellular ATP was measured to assess cell viability. Average values of three independent experiments are shown.

(A-B) Three different human NSCLC cell lines (H-1975, HCC-44, A549) were treated with the indicated dosages of VE-822 or PF-477736 over 48 hours. Only a mild viability reduction was observed after both treatments.

(C-D) Human SCLC cell lines (H-526, H-82, N-417, H-69) are sensitive to ATR inhibition (AZD-6738) and CHK1 inhibition (AZD-7762).

(E) *TP53*- and *RB1* mutation status, as well as *MYC*, *MYCN* and *CCND1* copy number status of H526, H82, H69, A549, H1975 and HCC44 cells. Data are derived from the Catalogue Of Somatic Mutations In Cancer (COSMIC) database.

(F) Re-analysis of *TP53* and *RB1* mutation data derived from human NSCLC cell lines curated in the COSMIC database. Mutation frequency is represented as a Venn diagram.

(G) Three different human SCLC cell lines (H-526, H-82, H-69) were transplanted into the flanks of athymic mice. For each cell line mice were allocated to a control cohort (not shown in E) and two treatment cohorts. Two cycles of treatment were applied. The VE-822 treated cohort received treatment weekly for three consecutive days at a dose of 30mg/kg by oral gavage. The PF-477736 treated cohort received treatment weekly for five consecutive days at a dose of 20mg/kg by intraperitoneal injection. Tumor volumes were assessed by serial digital caliper measurements.

## Full length membranes related to Figure 3C

## Full length membranes related to Supplemental Figure 3D

**Supplementary Figure 6: Original full-length blots related to Figure 3.**

The original full-length immunoblots related to Figure 3C (top) and Supplemental Figure 3D are shown.
