3

4 **Potassium permanganate foot-printing**

5 The potassium permanganate foot-printing assays were carried as previously
6 described¹. 1 μ M TBP and 125 nM TFB, 70 nM of RNAP were incubated in transcription
7 buffer containing 26 mM MgCl₂ and 0.5 mM DTT, in the presence or absence of 3 μ M
8 SsoTFE α/β , 700 nM TFS1 or TFS4. Samples were incubated for 5 min at 65°C before
9 the addition of 4 mM KMnO₄. After additional 5 min incubation at 65°C, the reaction
10 was stopped by addition of 1.5 μ l 2-mercaptoethanol. After Proteinase K treatment for
11 1 hour at 50°C, the samples were ethanol-precipitated. Samples were resuspended in
12 50 μ l 1 M piperidine and incubated at 90°C for 30 min. After chloroform-extraction,
13 samples were ethanol-precipitated and resuspended in 12 μ l formamide loading dye.
14 5 μ l of the samples were separated on 10% polyacrylamide, 7M Urea, 1 \times TBE
15 sequencing gel. Gels were dried for 1 h at 80°C under vacuum, visualized using
16 Typhoon FLA 9500 biomolecular imager (GE Healthcare) and analyzed using
17 ImageQuant TL Software (GE Healthcare).

53

54 **Supplementary figure 2: DNA templates used for EMSA and transcription assays**

55 (a) DNA template sequences used for abortive transcription, potassium permanganate

56 footprinting and PIC EMSA assays. The DNA template strand is in blue, the DNA non-

57 template strand is in cyan. For the heteroduplex template, -4 to -1 mismatch sequence

58 is highlighted in red. (b) SSV-T6 promoter 50 nt C-less cassette template used in RNA

59 cleavage and reactivation assays. (c) SSV-T6 promoter run-off template used in

60 promoter-directed transcription assays. (d) Nucleic acid scaffold sequences used in

61 elongation and TEC EMSA assays. The DNA template strand is in blue, the DNA non-

62 template strand is in cyan, and the RNA is in red.

63

64

65 **Supplementary figure 3: Effect of TFS4 on promoter melting.**

66 The effect of TFS4 on the melting of the SSV1-T6 promoter non-template strand was
 67 probed using potassium permanganate foot-printing assays. The promoter template
 68 for the assay is identical to the EMSA probes and includes a 4-nt heteroduplex region
 69 (register -4 to -1 relative to the TSS, highlighted in red, see also supplementary Fig.
 70 S2a). The reactive T residue at position -1 serves as positive control in this assay. The
 71 addition of RNAP in the presence of TBP and TFB induces three additional reactive T-
 72 residues at positions -5, -7 and -12, which reflect promoter melting in the PIC. The
 73 addition of TFE α/β increases their intensity in agreement with the role of TFE α/β during
 74 transcription initiation ¹. While the addition of TFS1 has little effect on DNA melting,
 75 TFS4 reduces permanganate reactivity to background levels, TFE α/β protects the PIC
 76 from TFS4 inhibition, in good agreement with our PIC EMSA. The position of all
 77 reactive T residues is indicated with an asterisk. G/A ladder and the corresponding
 78 non-template DNA strand sequence are shown on the left.

79

80 **Supplementary figure 4: TFS1 and TFS4 are incorporated into the TFE α/β -**
 81 **containing complete PIC.**

82 EMSA assay showing the stepwise assembly of PICs. The addition of TFE α/β to
 83 minimal PIC containing DNA-TBP-TFB-RNAP leads to both a slight upshift and an
 84 increase in signal intensity of the complete DNA-TBP-TFB-RNAP-TFE PICs. Adding
 85 either TFS1 or TFS4 induces a subtle but reproducible additional upshift showing that
 86 both can be incorporated into complete PICs. EMSA was carried out in a low salt (150
 87 mM) binding buffer and resolved on a 4-20% Tris-Glycine gel.

88

89

90

91 **Supplementary figure 5: Abortive transcription assay controls**

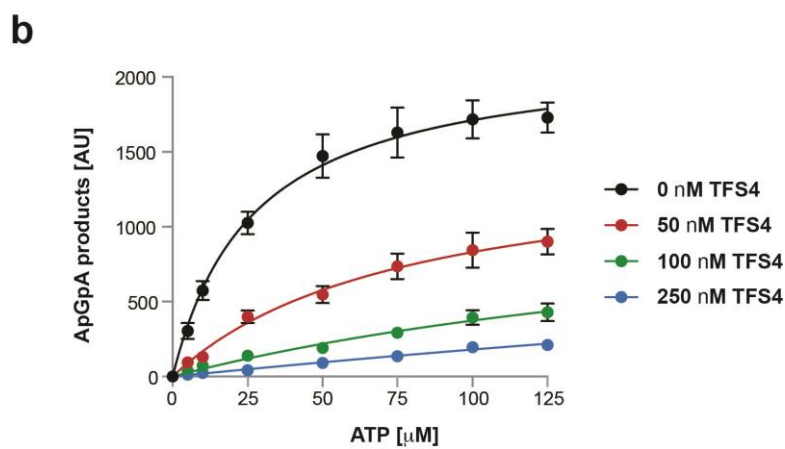

92 Abortive transcription assays measuring the addition of [α -³²P]-ATP (correct) or [α -³²P]-

93 CTP (noncomplementary) to the dinucleotide primer ApG on homoduplex (closed) and

94 heteroduplex (open) SSV1-T6 promoter templates in the presence or absence of 250

95 nM TFS4.

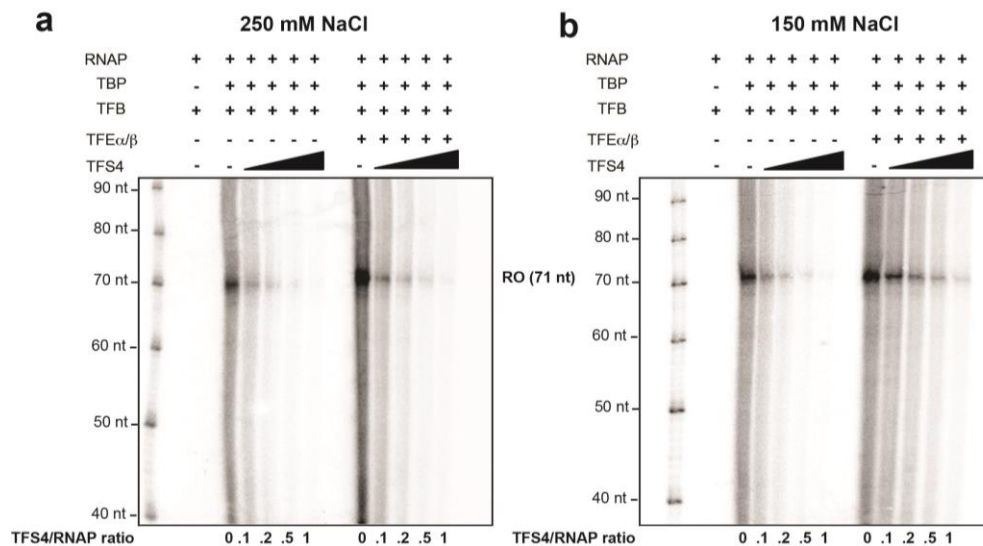

96

97

98 **Supplementary figure 6: Inhibitory effect of TFS4 on abortive initiation at varying**
 99 **substrate NTP concentrations.**

100 (a) We tested the effect of increasing substrate NTP concentration on TFS4 inhibition
 101 of transcription in abortive initiation assays at three TFS4 concentrations (50, 100 and
 102 250 nM). (b) The 3-nt abortive initiation products were quantified and plotted as a
 103 function of ATP concentrations for each TFS4 concentration. Error bars represent
 104 standard deviation based on three technical repeats.

105

106 **Supplementary figure 7: TFE α/β interference with TFS4 in promoter-directed**
 107 **transcription assays.**

108 TFS4 inhibition of transcription in the presence or absence of TFE α/β in promoter-
 109 directed transcription assays under **(a)** high- (250 mM) and **(b)** low-salt (150 mM)
 110 conditions. In contrast to its interference with PIC formation, TFS4 can inhibit promoter-
 111 directed transcription in the presence of TFE α/β , albeit less efficiently than without.
 112 This is likely due to the fact that TFS4 interferes with transcription elongation
 113 complexes. Reactions were carried out using the same conditions as in Figure 4a.

114

115

116 **Supplementary figure 8: TFS1 relieves TFS4 inhibition**

117 (a) The addition of TFS1 counteracts the inhibitory effects of TFS4 in a dose-
 118 dependent fashion. In order to compare the apparent relative affinities of RNAP:TFS1
 119 and RNAP:TFS4 complexes, transcription elongation assays were carried out in the
 120 presence of 100 nM TFS4 and varying concentrations of TFS1. This concentration of
 121 TFS4 is sufficient for complete inhibition of RNAP and therefore assumed to be higher
 122 than the apparent K_m (and K_D) for RNAP:TFS4 complexes. (b) Quantification of
 123 transcription elongation assay shown in (a). The relief of inhibition by TFS1 likely
 124 reflects the competition of TFS1 and TFS4 for RNAP binding. Under these conditions
 125 the IC_{50} of TFS1 is ~230 nM, i.e. the TFS1 concentration required to achieve 50% relief
 126 of TFS4 inhibition, where K_D (RNAP:TFS1) / K_D (RNAP:TFS4) = IC_{50} / [TFS4]. The
 127 amount of run-off products was quantified using ImageQuant TL Software (GE
 128 Healthcare). Error bars represent standard deviation from three technical repeats.

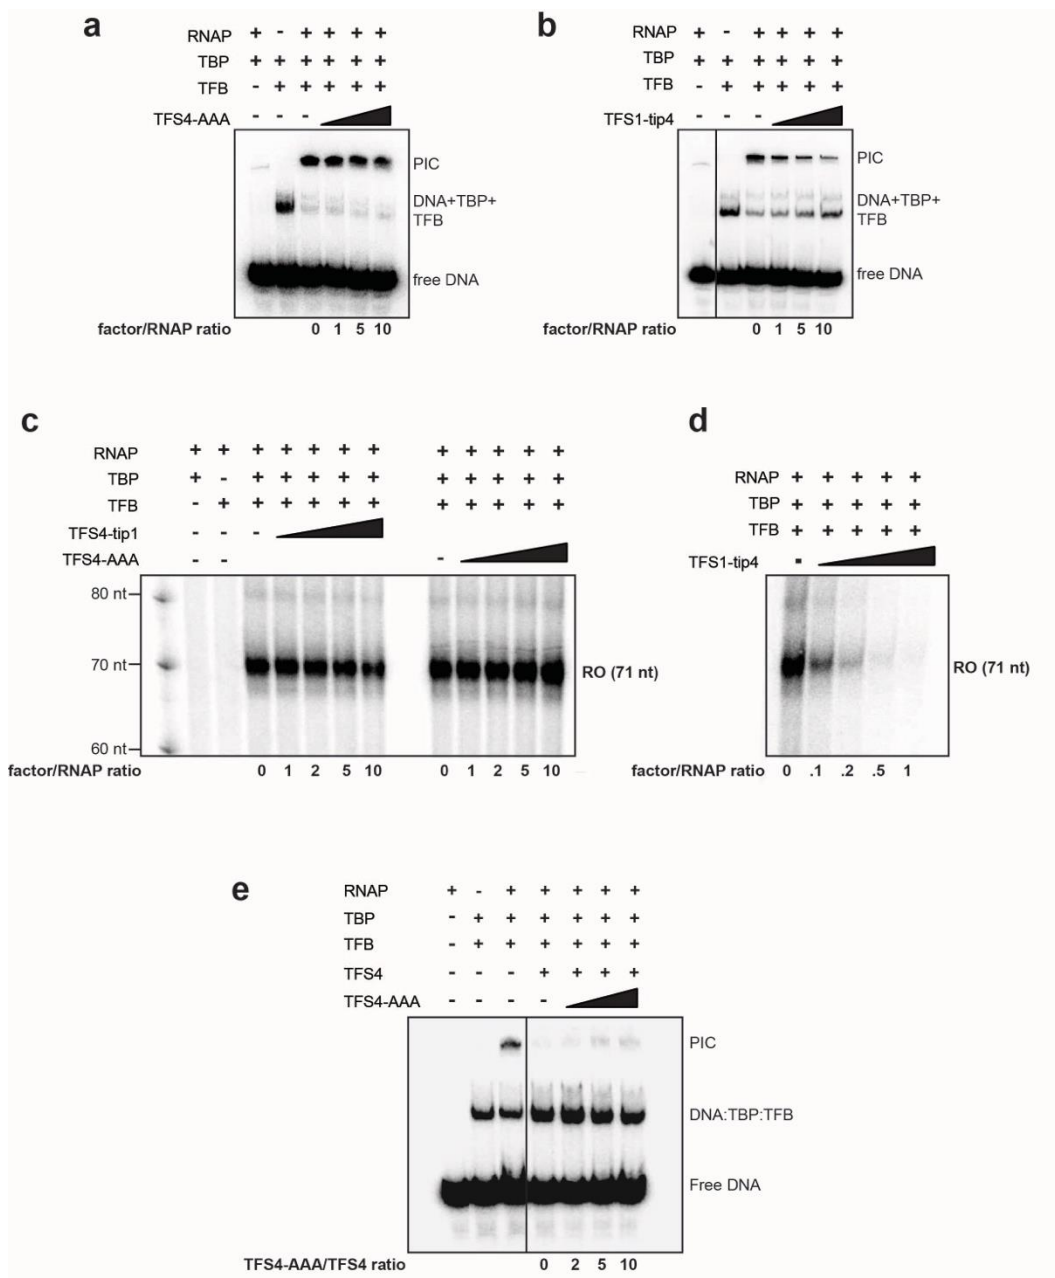

129

130

131

132

133

135

136 **Supplementary figure 9: Activity of TFS1 and TFS4 variants in EMSA and**
 137 **transcription run-off assays**

138 (a) and (b) EMSA with the minimal archaeal PIC complex (SSV1 T6 promoter DNA,
 139 TBP, TFB, RNAP) using TFS4-AAA (a) and TFS1-tip4 mutants (b) were carried out as
 140 in figure 3. (c) and (d) Promoter directed transcription assays on the SSV1 T6 promoter
 141 template in the presence of TFS4-tip1, TFS4-AAA (c) and TFS1-tip4 (d) mutants were

142 carried out as in figure 4. (e) Increasing amount of TFS4-AAA can only partially rescue
143 the formation of minimal archaeal PIC pre-incubated with TFS4.
144

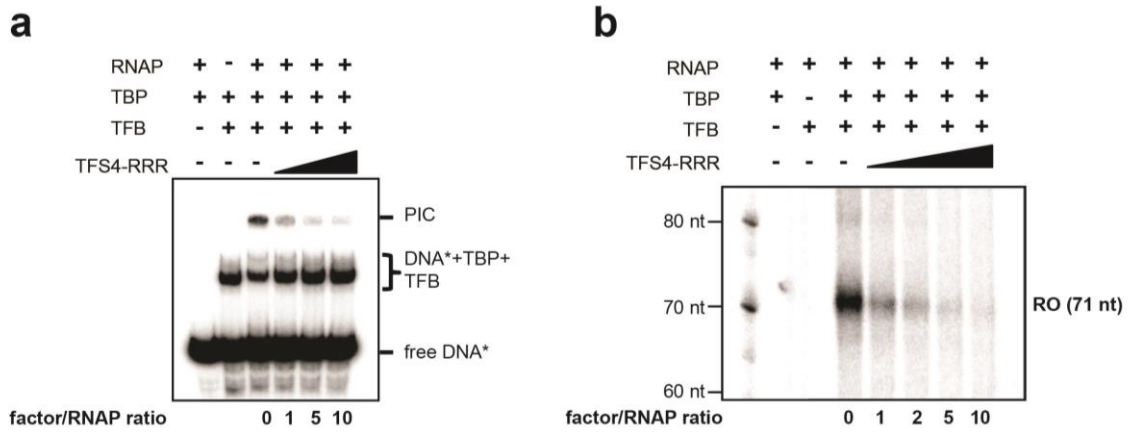

145

146 **Supplementary figure 10: The TFS1 tip motif confers transcript cleavage activity**
147 **to TFS4.**

148 Transcript cleavage assays were carried out as in figure 2. A chimeric TFS4-tip1
149 variant encompassing TFS4 and the TFS1 C-ZR tip motif stimulates transcript
150 cleavage in a dose-dependent fashion similar to TFS1. Reactions were carried out
151 using the same conditions as in Figure 2b.

152

153

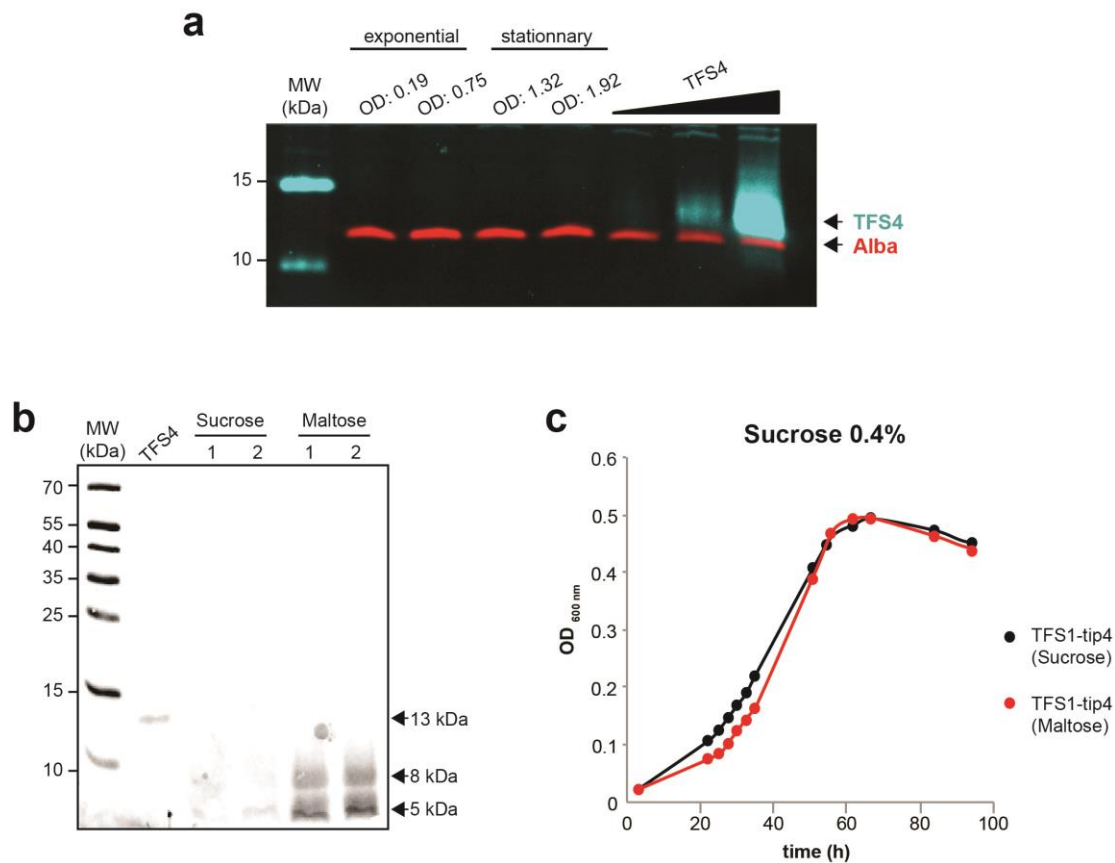

154

155 **Supplementary figure 11: Activity of TFS4-RRR in EMSA and transcription run-**
 156 **off assays**

157 (a) EMSA with the minimal archaeal PIC complex (SSV1 T6 promoter DNA, TBP, TFB,
 158 RNAP) using the TFS4-RRR mutant was carried out as in Figure 3a. (b) Promoter-
 159 directed transcription assays using the SSV1-T6 promoter template in the presence of
 160 the TFS4-RRR mutant was carried out as in Figure 4a.

161

162

163

164 **Supplementary figure 12: TFS4 expression in *Sulfolobus*.**

165 (a) TFS4 is not expressed during either exponential or stationary phase growth in
 166 *Sulfolobus solfataricus*. Multiplex Western blot using polyclonal antibodies raised
 167 against TFS4 and Alba (loading control) in cell lysates during different growth phases
 168 of *Sulfolobus solfataricus*. 9 µg of total protein was loaded in each lane. The last three
 169 lanes contain 0.7, 2.8 and 11.2 ng of recombinant TFS4 spiked into cell lysate in order
 170 to serve as positive control. Immunodetection was performed on three biological
 171 replicates. (b) Immunodetection of vector-driven ectopically expressed Sso TFS4 in *S.*
 172 *acidocaldarius* MW001 in sucrose (non-inducible) and maltose media (inducible).
 173 Western blot analysis was performed using polyclonal antibodies raised against Sso
 174 TFS4 on two biological replicates. (c) Recovery from TFS1-tip4 growth inhibition. The
 175 Saci strain harbouring the TFS1-tip4 expression plasmid was cultured under inducing
 176 (Maltose) or non-inducing conditions (Sucrose) and both cultures were subsequently

177 transferred to a non-inducing media (Sucrose). The growth curve is based on at
178 least three biological replicates.
