Abstract:

Objectives: To systematically review and compare the efficacy of all available home-based non-pharmacological treatments of depression.

Design: Systematic review and network meta-analysis of randomized controlled trials.

Data sources: Medline, Scopus, and CINAHL databases were searched since initiations to 7th August 2016.

Eligibility criteria: Randomized controlled trials comparing the efficacy of home-based non-pharmacological interventions with usual care of depressed patients were included in the review.

Main outcomes: Depression symptom scores and disease remission rates at the end of treatment.

Results: Seventeen studies were included in the review. Home-based non-pharmacological interventions were categorized as 1) home-based psychological intervention, 2) home-based exercise, 3) combined home-based psychological intervention with exercise, and 4) complimentary or alternative medicine. Complementary and alternative medicine approaches were excluded from the meta-analysis due to heterogeneity.

The standardized mean differences of post-treatment depression symptom scores between usual care groups and home-based psychological intervention, home-based exercise, and combined home-based psychological intervention with exercise were -0.57 (95%CI:-0.84, -0.31), -1.03 (95%CI:-2.89, 0.82), and -0.78 (95% CI:-1.09,-0.47), respectively. These results suggest that only home-based psychological intervention and combined home-based psychological intervention with exercise could significantly decrease depression scores. Compared with usual care groups, the disease remission rate was also significantly higher for home-based psychological intervention (pooled risk ratio = 1.53; 95% CI: 1.19, 1.98) and combined home-based psychological intervention with exercise (pooled risk ratio = 3.47; 95% CI: 2.11, 5.70). Of all the studied interventions, combined home-based psychological intervention with exercise had the highest probability of resulting in disease remission.

Conclusion: Our study confirms the efficacy of home-based psychological intervention and combined home-based psychological intervention with exercise in the treatment of depression. Combined home-based psychological intervention and exercise was the best treatment and should be considered for inclusion in clinical guidelines for managing depression.

Strengths and limitations of this study

- Our analysis provides the first comprehensive review of the efficacy of home-based non-pharmacological interventions in treating depression.
- A comprehensive search was undertaken to identify as many relevant studies as possible.
- We performed a network meta-analysis to compare the efficacy of home-based interventions in order to identify the best treatment regimen.
- The quality of included studies in the area of allocation concealment was not optimal.
- Participants in our included studies were aware of their own intervention and the outcomes were subjective.

INTRODUCTION

Recent studies have highlighted the international recognition of depression as one of the leading global burdens of disease (GBD)¹. Depression is associated not only with greater morbidity and mortality but also with increasing health service use and costs². In addition, untreated depression has been recognized as a strong predictor of poor health outcomes in elderly³⁻⁵ and adult patients with chronic disease⁶⁻⁸.

Both pharmacological and non-pharmacological interventions, such as psychotherapy or supervised exercise, have been accepted as standard treatments of depression. However, concerns about drug side effects and dependency appear to make patients prefer psychological interventions. One study showed that around 70% of depressed patients were non-compliant with antidepressants because of concerns about their side effects⁹. Even though non-pharmacological interventions were preferred over antidepressants^{10 11}, only a very small percentage of patients referred for psychotherapy were able to enter and complete this treatment¹². This inconsistency between patient preference and low rates of initiation and adherence to treatment could be a consequence of barriers to obtaining treatment. Non-pharmacological interventions are usually clinic or hospital-based and require visits on a weekly or monthly basis. In one study, 70% of patients reported structural barriers preventing them from attending psychotherapy sessions regularly and cited time constraints, transportation problems and cost as being significant obstacles¹³.

Among older patients, whose prevalent rate of depression is very high, these problems were aggravated by concurrent medical illness, social isolation, functional impairment or being home-bound¹⁴⁻²⁰. Overcoming these barriers by providing interventions in patients' own homes may achieve better treatment adherence and thereby greater treatment success than clinic or hospital-based interventions.

Home-based non-pharmacological interventions, such as problem solving therapy²¹⁻²⁵ and home-based exercise^{26 27}, have developed over several years. Although some studies have suggested that these approaches can improve depressive symptoms and rates of remission when compared with standard usual care^{26 28 29}, other studies have reported conflicting results^{27 30 31}. Until now, no study has systematically reviewed all possible home-based non-pharmacological interventions and summarised the treatment effect of each intervention. Our systematic review and network meta-analysis was, therefore, undertaken with the aim of reviewing all available home-based

1
2
3 non-pharmacological interventions, pooling the effect sizes of each intervention on symptom
4 improvement and indirectly comparing treatment efficacy between the different interventions. The
5 results of this review should be useful for identifying the most beneficial home-based non-
6 pharmacological interventions and for informing clinical guidelines for treating depression.
7
8
9

10 **METHODS**

11 **Search strategy**

12
13
14
15 Relevant studies were identified using Medline, Scopus, and CINAHL databases searched
16 from inception to 7th August 2016. Reference lists of included studies were also explored. Search
17 terms and search strategies for each database are presented in a Supplementary Appendix.
18
19

20 **Selection of studies**

21
22
23
24 Initially studies were selected from titles and abstracts by two independent reviewers (K.S.
25 and T.A.). Full articles were retrieved to aid decision making if decision could not be made based on
26 titles and abstracts. Disagreement between the two reviewers was resolved by discussion.
27 Percentage agreement between the two reviewers was estimated using kappa statistics.
28
29
30

31 **Inclusion criteria**

32
33
34 Randomized-controlled trials published in English were eligible for the review if they met all of
35 the following criteria:
36
37

- 38
39 1. Study participants were adults aged more than 18 years with a diagnosis of any degree of
40 depressive disorder using the criteria of the Diagnostic and Statistical Manual of Mental
41 Disorders 4th Edition (DSM-IV) or any diagnostic tool used for diagnosis or screening for
42 depression. Participants who were children, adolescents or postpartum women were
43 excluded.
44
45
46
47
- 48 2. Interested interventions were non-pharmacological and provided in the patient's home, such
49 as cognitive behavioral therapy, problem solving therapy, family therapy, or home-based
50 exercise.
51
52
- 53 3. Treatment comparison was the standard care of depression in outpatient clinics or hospital
54 settings.
55
56
57
58
59
60

4. Outcomes were measured by the level or severity of depressive symptoms or the incidence of disease remission at the end of the intervention.
5. Studies provided sufficient data for analysis, such as number of participants (n), mean depression score, standard deviation (SD) for each intervention group, and the number of patients per intervention group with or without disease remission.

Data extraction

Two reviewers (KS and TA) independently used a standardized data record form to extract baseline characteristics of included studies and outcomes of interest. Disagreement between the two reviewers was resolved by discussion and corresponding authors of studies were contacted if information was incomplete.

Interested interventions

Home-based non-pharmacological intervention was defined as any care or management of depression provided by health care professionals at a patient's place of residence. Home-based interventions had to have a clear and definite objective. Home visits that provided only health-education, social or emotional support were, therefore, excluded from this study.

Outcomes of interest

The outcomes of interest were depressive symptom scores and disease remission rates at the end of treatment. Disease remission was defined according to the criteria of the original article. Included studies used several tools for measuring the severity of depressive symptoms, namely the Hamilton Depression Rating Scale (HAM-D)^{21 22 30 32 33}, Patient Health Questionnaire-9 (PHQ-9)^{24 34}, Geriatric Depression Scale (GDS)^{23 26 28}, Hopkins Symptom Checklist-20 (HSCL-20)^{35 36}, Montgomery Asberg Depression Rating Scale (MADRS)^{18 25 27}, Beck Depression Inventory-Fast Screen (BDI-FS)³⁷ and Center of Epidemiologic Studies Depression Scale (CES-D)³⁸. These tools have different score ranges (HAM-D = 0-53, PHQ-9 = 0-27, GDS = 0-15, HSCL-20 = 0-4, MADRS = 0-60, BDI-FS = 0-21, and CES-D = 0-60) with higher scores in all tools representing increasing severity of depressive symptoms.

Risk of bias assessment

1
2
3 To assess the quality of included studies, a risk of bias assessment tool³⁹ was applied by two
4 independent reviewers (K.S., T.A.). Six domains were evaluated as follows: 1) random sequence
5 generation 2) allocation concealment 3) blinding of participants and personnel 4) blinding of outcome
6 assessors 5) incomplete outcome data 6) selective outcome reporting 7) other sources of bias. The
7 quality of the studies was classified as being at high, unclear, or low risk of bias. Disagreement
8 between the two reviewers was settled by discussion.
9
10
11
12
13

14 **Statistical analysis**

15
16
17 Because depression scores were measured differently among the studies, for direct
18 comparison the mean differences of depressive scores between intervention and control groups were
19 estimated for each study and then were pooled using the standardized mean difference (SMD).
20 Heterogeneity between studies was estimated by Q test and I^2 statistic. Heterogeneity between
21 studies was considered if the P-value from Q test was less than 0.10 or if I^2 was equal to or greater
22 than 25%⁴⁰. If heterogeneity was presented, the SMD was estimated by applying the random effect
23 model. Otherwise the fix effect model was applied.
24
25
26
27
28
29

30
31 For dichotomous outcomes, relative risks (RR) of disease remission were calculated for each
32 study. The random effect model was used for pooling RR if there was evidence of heterogeneity
33 between studies. Otherwise the inverse variance method was used. Sources of heterogeneity were
34 explored by considering possible factors one by one in a meta-regression model (e.g. mean age,
35 severity of depression at baseline and types of intervention delivery).
36
37
38
39

40
41 For network meta-analysis, treatment effects for each study were estimated using a two-stage
42 network meta-analysis. Firstly, summary data was expanded into individual patient data using the
43 'expand' command in STATA program. Binary regression was applied to estimate log (RR) and
44 variance-covariance of each treatment using 'mvmeta' make command. A multivariate random effect
45 meta-analysis was used to calculate the pooled RRs and their 95% confidence intervals (CI). Riley's
46 method was used for considering subject-study correlation. Treatment ranking was made according to
47 the linear predictor of each study. Disagreement between direct and indirect estimations
48 (inconsistency assumption) was examined by measuring the inconsistency factor, i.e. the difference
49 between lnRRs estimated from direct and indirect meta-analyses.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Publication bias was assessed using Egger test and funnel plot. If the funnel plot showed
4 asymmetry, a contour enhanced funnel plot was performed to explore whether asymmetry was the
5 result of heterogeneity between studies or arisen from publication bias. All analyses were performed
6 using STATA version 14. A two-sided test with P-value less than 0.05 was considered statistically
7 significant, except for the Q test, in which a P-value less than 0.10 was applied.
8
9

10 11 12 **Patient involvement**

13
14
15 Patients were not involved in the design of the study, development of outcome measures, or
16 conduct of the study. We did not ask patients for advice on interpreting or writing up results. There are
17 no plans to disseminate the results of the research to study participants.
18
19

20 21 **RESULTS**

22
23 We identified 385, 534, 255, and 2 articles from Medline, Scopus, CINAHL databases and
24 reference lists respectively. After deleting duplications, the titles and abstracts of 768 studies were
25 reviewed. Finally, 17 studies met our inclusion criteria and were eligible in the review (Figure 1).
26 Agreement of study selection between the two reviewers was high at 86.7% (Kappa = 0.50).
27
28
29

30 31 32 **Study participants**

33
34 The baseline characteristics of included studies are presented in Table 1. The type and
35 severity of depression of participants differed between studies. Four studies^{25 28 32 33} included patients
36 with major depressive disorder, four^{22 23 36 38} included patients with minor depression and nine^{18 21 24 26}
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
27 30 34 35 37 included patients with mixed severities of depression. Ten studies included elderly
patients^{18 21-26 28 36 38} while seven studies included adults with ages greater than 18 years^{27 30 32-35 37}.
Ten studies included depressed patients with other co-morbidities (i.e. epilepsy³⁵, heart diseases^{22 30}
³⁴, disability¹⁸, and mild to moderate cognitive impairment²⁵). Twelve studies^{21 23 24 26-28 32 33 36-38}
included patients without co-morbidity. Use of anti-depressants at baseline varied widely between
studies, ranging from 0% to 95%.

52 53 54 **Home-based interventions**

55
56
57
58
59
60
The composition of home-based non-pharmacological interventions differed among the
included studies. The effect of interventions on depressive symptoms was, therefore, analyzed using

1
2
3 four general categories: 1) home-based psychological intervention 2) home-based exercise
4
5 3) combined home-based psychological intervention with home-based exercise 4) complementary or
6
7 alternative medicine. Eight, 3 and 3 studies compared home-based psychological intervention with
8
9 usual care, home-based psychological intervention with usual care, and combined home-based
10
11 psychological intervention with home-based exercise with usual care, respectively. One study
12
13 compared the efficacy between home-based psychological intervention, home-based exercise,
14
15 combined home-based psychological intervention with home-based exercise, and usual care. Since
16
17 interventions in the category of complementary or alternative medicine were heterogeneous, they
18
19 were not included in the meta-analysis but were subjected to qualitative analysis. Details of each
20
21 home-based intervention are summarised below:

22 ***Home-based psychological intervention***

23
24 Home-based psychological intervention was classified as home-based problem-solving
25
26 treatment or home-based cognitive behavioral therapy.

27 28 29 1. *Home-based problem-solving treatment* (6 studies^{21 22 24 25 28 29})

30
31 Home-based problem-solving treatment (PST) is a skill-enhancing behavioral treatment of
32
33 depression usually delivered by social workers and psychologists. This approach assumes that
34
35 depressive symptoms are caused and maintained by problems of daily life and that these can be
36
37 reduced by identifying and addressing them systematically. Each PST session comprises 1) defining
38
39 and formulating the nature of the depressive problem 2) generating a range of alternative solutions to
40
41 the problem 3) systematically evaluating the possible consequences of each solution then selecting
42
43 the most appropriate one 4) monitoring and evaluating the actual outcome. In addition, PST identifies
44
45 patients' pleasurable activities and encourages them to participate in these activities.

46 47 2. *Home-based cognitive behavioral therapy* (CBT) (3 studies^{30 37 38})

48
49 The aim of CBT is to modify the dysfunctional emotions, behaviours, and thoughts of
50
51 depressed patients. This type of intervention was identified in 3 studies, of which 2 studies were CBT-
52
53 based bibliotherapy. In this approach, participants received self-help books or leaflets that included
54
55 instruction on cognitive behavioral self-help, mood management skills, and tasks to practice. During
56
57 the intervention period, participants were visited by home care nurses or contacted by telephone by

1
2
3 study investigators to assess their symptoms and encourage them to follow the course at their own
4
5 pace.

7 ***Home-based exercise***

8
9
10 Home-based exercise was employed in 4 studies. Exercise included both progressive
11 resistance training, aerobic exercise^{26 27} and aerobic exercise only^{30 33}. Participants were required to
12 perform the exercises for at least 30 minutes three times a week.
13
14

15 ***Combined home-based psychological intervention with exercise***

16
17
18 Home-based psychological intervention combined with exercise was the interested
19 intervention in 4 studies. Each of these applied aerobic exercise as a home-based exercise but
20 psychological therapies differed among them (PST in two studies^{35 36}, cognitive behavioral therapy in
21 one study³⁰ and family therapy with bereavement counselling and social interventions in one study¹⁸).
22
23
24
25

26 ***Complementary or alternative medicine***

27
28
29 This intervention refers to a broad set of health care practices or activities that are not
30 integrated into the dominant health care system. This type of intervention was used in 2 studies. One
31 involved home-based deep-breathing exercise³⁴ aimed at stimulating a relaxation response, (i.e. to
32 decrease arousal, heart rate and blood pressure, and to reduce responsiveness of the sympathetic
33 nervous system). Deep-breathing exercises can also help patients to disregard negative and
34 distracting thoughts. Patients were trained by experienced nurses to breathe at a rate of six breaths
35 per minute. During the treatment period, this was undertaken in a quiet environment for a period of
36 ten minutes, three times each day.
37
38
39
40
41
42
43

44
45 The other intervention employed a spirituality teaching programme⁴¹ aiming to promote
46 contemplation of the inter-relation between meaning and purpose, connectedness with others, nature
47 or the divine, and values such as compassion, love, justice, and forgiveness. The programme
48 comprised eight sessions involving explanation of the divine aspect of the self, teaching breathing and
49 visualization practice, helping patients to connect with the divine through prayer or meditation, letting
50 go of regret and fostering gratitude, practicing self-awareness relating to the five senses, and building
51 upon connectedness with others. Participants were also advised to avoid forming expectations and to
52
53
54
55
56
57
58
59
60

1
2
3 refrain from judging outcomes. Initially patients participated in a workshop run by psychiatrists and
4
5 were then required to practice by themselves with the help of audio CDs.
6

7 8 **Treatment comparison**

9
10 Usual care, defined as the standard care of depression managed in a clinic or hospital setting,
11 was applied as a treatment comparator for all studies. In addition to usual care, three studies^{25 26 29}
12 included home visits and two^{21 34} included telephone support. However, these interventions provided
13 education about depression together with general social or emotional support but did not offer specific
14 psychological help or exercise. With the exception of one study⁴¹, almost all used anti-depressant
15 medication as a co-intervention but the decision to initiate or maintain this was dependent on the
16 judgement of patients and their physicians.
17
18
19
20
21
22

23 **Risk of bias assessment**

24
25
26 Results of risk of bias assessment are presented in Supplementary Table 1. Most of the
27 studies (14 studies) reported low risk of bias in the domain of random sequence generation, while 3
28 studies^{21 22 30} reported unclear risk. For allocation concealment, 11 studies^{18 21 22 25-30 37 38} had unclear
29 risk of bias, while 6 studies^{24 33-36 41} had low risk of bias. All studies reported high risk of bias in the
30 domain of blinding of participants and personnel and low risk of bias in other domains. Ten studies^{18 22}
31

57
58
59
60
25-27 29 30 33 35 41 had low risk of bias for blinding of outcome assessors, whereas 7 studies^{21 24 28 34 36-38}
had unclear risk. For the domain of incomplete outcome data, 13 studies^{18 22 24-27 29 30 33 35 36 38 41}
reported low risk of bias and 4 studies^{21 28 34 37} reported high risk. Almost all studies (16 studies) had
low risk of bias for selective outcome reporting, while only one study³⁵ had high risk of bias.

43 **Pooled mean difference of depression score**

44 *Home-based psychological intervention vs usual care*

45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
Nine studies were analyzed^{21 22 24 25 28-30 37 38} comparing home-based psychological
intervention with usual care (N = 739). Depression scores were assessed at the end of treatment,
which ranged from 6 to 48 weeks. The mean differences and 95% CIs of depression scores for each
study are presented in Table 2. SMD of home-based psychological intervention versus usual care
was -0.57 (95% CI: -0.84, -0.31), suggesting that home-based psychological intervention can
significantly decrease depression scores when compared with usual care.

Moderate heterogeneity was found between studies, with I^2 of 63.5%. Sources of heterogeneity were explored but none of the factors decreased I^2 . Subgroup analyses were performed according to the severity of depression (i.e. major depressive disorder (MDD), minor depression and mixed severity of depression). These showed that SMDs in patients with MDD, minor depression, and mixed severity of depression were -0.95 (95% CI: -1.35, -0.55; $I^2 = 16.5\%$), -0.61 (95% CI: -1.28, 0.06; $I^2 = 82.1\%$), and -0.41, (95% CI: -0.62, -0.19; $I^2 = 0\%$) respectively (see Supplementary Figure 1). These suggest that home-based psychological intervention reduces depression scores significantly in the groups of MDD and mixed severity of depression. In addition, the efficacy of this intervention in patients with MDD was better than the efficacy in patients with minor depression.

Home-based exercise vs usual care

Three studies^{26 30 33} (N = 321) were pooled to compare the effect of home-based exercise with usual care. The SMD was -1.03 (95% CI: -2.89, 0.82; $I^2 = 97.9\%$) (Table 2 and Supplementary Figure 2A). The mean depression score in the home-based exercise group was therefore 0.03 units lower than the mean depression score in the usual care group. However, this effect did not reach statistical significance.

Combined home-based psychological intervention with exercise vs usual care

Only two studies^{30 36} (N = 169) had sufficient data for pooling the effect on the depression score of combined home-based psychological intervention with exercise. Mean depression scores were measured at the ends of the treatments, namely at 12 weeks³⁰ and 24 weeks³⁶. Table 2 shows the mean depression scores and 95% CIs for each study. SMD was -0.78 (95% CI: -1.09, -0.47; $I^2 = 0.0\%$) (Supplementary Figure 2B). This indicates that patients receiving combined home-based psychological intervention and exercise had significantly lower mean depression scores (by 0.78 units) than patients receiving usual care.

Pooled risk ratio of disease remission

Home-based psychological intervention vs usual care

Four studies (N = 459) comparing the effectiveness of home-based psychological intervention with usual care had remission rates as their outcome of interest. Remission from depression was defined as HAMD score ≤ 7 in one studies²⁵, PHQ-9 ≤ 4 in one study²⁴, BDI < 4 in one study³⁷ and

1
2
3 CES-D < 16 in one study³⁸ (Table 3). The pooled RR was 1.53 (95% CI: 1.19, 1.98) (Supplementary
4 Figure 3), suggesting that patients receiving home-based psychological intervention were
5 approximately 1.7 times more likely to have remission from depression than patients receiving usual
6 care. The results among studies were homogeneous with I^2 of 0%.

10 *Home-based exercise vs usual care*

11
12
13 Two studies (N = 248) reported their outcome as disease remission and had sufficient data
14 for pooling. Disease remission was defined as HAMD score ≤ 7 ³³ or symptoms no longer meeting the
15 criteria for major and minor depression according to DSM-IV criteria²⁷ (Table 3). The pooled RR was
16 0.99 (95% CI: 0.79, 1.24; $I^2 = 0.0\%$) (Supplementary Figure 4A), indicating that there was no
17 significant difference between home-based exercise and usual care in the likelihood of having
18 remission from depression.
19
20
21
22
23

24 *Combined home-based psychological intervention and exercise vs usual care*

25
26
27 Three studies (N = 279) were pooled to compare remission rates between combined
28 psychological intervention and usual care. Disease remission was defined as HSCL-20 score < 0.5 for
29 two studies^{35 36} but in Banerjee's study¹⁸ the outcome was not clearly defined (Table 3). Pooled RR
30 was 3.47 (95% CI: 2.11, 5.70; $I^2 = 19.7\%$) suggesting that the combination of home-based
31 psychological intervention and exercise significantly increased the likelihood of remission from
32 depression when compared with usual care (Supplementary Figure 4B).
33
34
35
36
37
38

39 **Network meta-analysis**

40 *Disease remission rate*

41
42
43
44 Nine studies (N = 987) were included in the network meta-analysis. Supplementary Figure 5
45 shows the network plot of home-based psychological intervention, home-based exercise, combined
46 home-based psychological intervention with exercise, and usual care. Size of node and edge reflect
47 the number of studies and patients respectively. From the plot, usual care was the common
48 comparator and had the largest sample size of the four treatment regimes. Home-based
49 psychological intervention versus usual care had the largest number of studies.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Pooled RRs for each treatment comparison are presented in Figure 2. Compared with usual
4 care, only combined home-based psychological intervention with exercise and home-based
5 psychological intervention alone significantly increased the likelihood of disease remission, with
6 pooled RRs of 3.12 (95% CI: 1.71, 5.70) and 1.50 (95% CI: 1.17, 1.93) respectively. In addition, the
7 incidence of disease remission in home-based psychological intervention and combined home-based
8 psychological intervention with exercise groups was significantly higher than in the home-based
9 exercise group, having pooled RRs of 1.49 (95% CI: 1.07, 2.10) and 3.10 (95% CI: 1.63, 5.90),
10 respectively. When compared with home-based psychological intervention alone, combined home-
11 based psychological intervention with exercise also significantly improved the rate of disease
12 remission (pooled RR = 2.08; 95% CI: 1.08, 3.99).
13
14
15
16
17
18
19
20
21

22 Treatment ranking was assessed by estimating the probability of each treatment being the
23 best. This yielded probabilities of 99.5%, 0.5%, and 0% for combined home-based psychological
24 intervention with exercise, home-based psychological intervention alone, and home-based exercise
25 respectively. Combined home-based psychological intervention with exercise therefore emerged as
26 the best intervention for achieving remission from depression.
27
28
29
30
31

32 Applying inconsistency assumptions to the treatments, inconsistency factors were calculated
33 as 0.020 (Z=0.183, P-value=0.912) for home-based psychological intervention, -0.018 (Z=0.110, P-
34 value=0.913) for home-based exercise, and 0.106 (Z=0.107, P-value=0.915) for combined home-
35 based psychological intervention with exercise. These figures find no significant difference between
36 the direct and indirect comparison of estimated treatment effects.
37
38
39
40
41

42 **Efficacy of complementary or alternative medicine**

43
44 Results from a study comparing the efficacy of home-based deep-breathing exercises with
45 usual care showed that patients receiving this intervention had significantly lower depression scores
46 than patients receiving usual care, with a mean difference of -1.34 (95% CI: -1.17, -0.17). Another
47 study compared the efficacy of home-based spiritual therapy with usual care. Findings from this study
48 suggested that home-based spiritual therapy could significantly decrease depression scores when
49 compared with usual care, with a mean difference of -1.11 (95% CI: -1.57, -0.65). In addition, this
50 study found that patients receiving home-based spiritual therapy were more likely to have disease
51
52
53
54
55
56
57
58
59
60

1
2
3 remission than patients receiving usual care. The risk ratio of disease remission (defined as HAMD
4 score ≤ 7) from this study was 13.85 (95% CI: 1.88, 101.74)
5
6

7 **Publication bias**

8
9
10 Egger tests and Funnel plots did not suggest any publication bias for pooling the effect of
11 home-based psychological intervention (coefficient = -0.05, P-value = 0.882) and home-based
12 exercise (coefficient = 6.94, P-value = 0.818) (see Supplementary Figure 6A and 6B). For combined
13 home-based psychological intervention and exercise, the Egger test did not suggest publication bias
14 but a funnel plot showed asymmetry (Supplementary Figure 7A). The cause of this asymmetry was
15 explored by performing a contour enhanced funnel plot which showed that most of the studies fell
16 inside the significant area. The asymmetrical plot may, therefore, result from a small study effect
17 rather than heterogeneity between studies (see Supplementary Figure 7B).
18
19
20
21
22
23

24 **DISCUSSION**

25
26
27 Our study found that a combination of home-based psychological intervention with exercise
28 and home-based psychological intervention alone both significantly decreased depressive symptoms
29 and increased the likelihood of disease remission when compared with usual care. However, we
30 could not demonstrate any benefit of home-based exercise alone when compared with usual care. In
31 addition, combined home-based psychological intervention with exercise had the highest probability of
32 remission from depression compared both with home-based psychological intervention and home-
33 based exercise.
34
35
36
37
38
39

40
41 The effectiveness of clinic-based psychological intervention for treating depression has been
42 confirmed by previous studies⁴²⁻⁴⁴. The results of our study also support the efficacy of this
43 intervention when performed in the patient's home. In our review, the majority of participants in the
44 included studies were depressed patients with comorbidities such as epilepsy³⁵ or heart disease^{22 30}
45³⁴, or were elderly patients with disabilities¹⁸ or cognitive impairment²⁵. These groups have a high
46 prevalence of depression and should therefore be expected to receive a significant share of mental
47 health provision. However, their ability to access conventional clinic-based mental health services is
48 restricted by mobility problems and low motivation to seek help. With its ability to overcome these
49 barriers, home-based psychological intervention is particularly appropriate in these situations.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 In addition to demonstrating the efficacy of home-based psychological intervention overall,
4 subgroup analysis within our study raises an interesting point. Home-based psychological intervention
5 decreased symptoms of depression for all types of depression but the effect was statistically
6 significant only in patients with MDD and mixed severity depression, not for those with minor
7 depression. This inconsistent finding may result from the so called “ceiling” effect. The level of
8 depressive symptoms in minor depression is relatively low at baseline when compared with major
9 depression, which could limit the potential for symptom improvement⁴⁵. This ceiling effect was also
10 found in the studies reviewing the use of antidepressant medication for minor depressive symptoms.
11
12
13
14
15
16
17

18 The rationale for home-based exercise rests on the theory that increasing physical activity
19 can improve depressive symptoms through psychological and physiological routes. Exercise serves
20 as a distraction from worries and depressive thoughts, increases self-efficacy, and gives a sense of
21 mastery. Possible physiological mechanisms include an increase in body temperature, leading to a
22 feeling of relaxation and reduced muscle tension, an increase in levels of endorphins related to
23 positive mood and a sense of well-being, and increases in the availability of the central
24 neurotransmitters dopamine, norepinephrine and serotonin^{43,46 47}. Although the advantages of clinic-
25 based or supervised exercise to treat depression have been confirmed by previous literature⁴⁸, our
26 study found no benefit from home-based exercise in ameliorating depressive symptoms. The
27 difference in these findings may be explained by poorer treatment compliance in the home-based
28 exercise group, as to achieve significant benefit patients have to practice the exercise programme at
29 a prescribed intensity and frequency. Lack of motivation and inattention are common symptoms in
30 depression and may account for unsupervised patients failing to achieve the prescribed levels of
31 activity when compared with those given encouragement through supervision. This assumption
32 corresponds with findings from the home-based exercise studies^{26 27} that the physical health of
33 patients in this group (i.e. cardio-respiratory capacity, BMI, and lower limb strength), the surrogate
34 endpoints of exercise intervention, did not change significantly from baseline.

43
44
45
46
47
48
49

50 Although our study did not find any advantages of home-based exercise over usual care,
51 when combined with psychological intervention the combined approach had a significantly greater
52 benefit than either of these interventions alone. The combination may have a synergistic effect, with
53
54
55
56
57
58
59
60

1
2
3 psychological intervention improving motivation to initiate and maintain an exercise programme while
4 the latter in turn enhances the benefits of psychological intervention.
5
6

7 Looking at complimentary or alternative medicine approaches, results from Chung et al and
8 Rickhi et al showed that home-based deep-breathing training and spiritual teaching programmes
9 could significantly reduce depressive symptoms when compared with usual care. However, these two
10 studies had small sample sizes and included specific populations, namely coronary heart disease
11 patients for Chung's study and middle-aged females for Rickhi's study. Their findings may not,
12 therefore, be generalizable to other populations.
13
14
15
16
17
18

19 **Strengths and limitations**

20
21 Our study has several strengths. Given the potential of home-based interventions to treat
22 depression and the increasing use of these interventions, our analysis provides the first
23 comprehensive review of the efficacy of home-based interventions in treating depression. A
24 comprehensive search was undertaken to identify as many relevant studies as possible and two
25 reviewers selected the studies independently with a high level of agreement. Selection bias was,
26 therefore, unlikely. In addition, we performed a network meta-analysis to compare the efficacy of all
27 available home-based interventions in order to identify the best treatment regime.
28
29
30
31
32
33
34

35 We are aware that our study may have some limitations. Firstly, the quality of included studies
36 in the area of allocation concealment was not optimal. The results from our study might, therefore, be
37 affected by selection bias and should be interpreted with caution. Secondly, participants in our
38 included studies were aware both of their own intervention and their subjective outcome, including the
39 self-reported depression score. However, in most of the included studies this bias from non-blinded
40 intervention was minimized by blinding the outcome assessors. Thirdly, some of the included studies
41 considered home visits as a treatment comparator. This may have resulted in an underestimated
42 treatment effect for the home-based interventions.
43
44
45
46
47
48
49

50 **Clinical implication and further study**

51
52 Depression is a common disorder, particularly among the elderly and in those with a chronic
53 disease. Many of these patients have difficulty accessing mental health services due to physical
54 disabilities and transportation problems. Home-based interventions to treat depression have the
55
56
57
58
59
60

1
2
3 potential to overcome these barriers and have been shown by our study to be effective. This
4 information should prove helpful when designing clinical guidelines. However, there are obvious
5 logistical differences between home-based treatments for depression and conventional clinic-based
6 care. Our study has not investigated these aspects of treatment design and, in particular, has not
7 considered manpower implications or transport costs. An economic evaluation study is needed before
8 general implementation of a home-based care model can be recommended unequivocally.
9
10
11
12

13
14
15 Although a randomized-controlled trial is considered to be the gold standard for therapeutic
16 research, in a real world setting this design may not be ideal for examining patient preferences and
17 adherence to treatment. To maximize treatment efficacy, studies should determine the effects of
18 patient preferences for different treatment approaches and modes of delivery as well as examine the
19 factors that influence these preferences.
20
21
22

23 24 **CONCLUSION**

25
26
27 Our study has confirmed the efficacy both of home-based psychological intervention and
28 combined home-based psychological intervention with exercise in decreasing symptoms of
29 depression and improving rates of remission. In addition, the combination of home-based
30 psychological intervention and exercise has the highest probability of being the best treatment out of
31 all available home-based interventions. This approach should, therefore, be considered when
32 formulating clinical guidelines for treating depression.

PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	5, 6
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	-
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	6, 7
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	6
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Supplementary Appendix
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	6
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	7
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	7
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	8
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	8
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I^2) for each meta-analysis.	8

PRISMA 2009 Checklist

Page 1 of 2

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	9
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	8
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	9, Figure 1
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	9, 10, 11, 12 & Table 1
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	12 & Supplementary Table 1
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Tables 2 & 3 Figure 2 Supplementary Figure 1, 2, 3, 4
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	12-16
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	16
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	12-16
DISCUSSION			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	16-19
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	18
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	19
FUNDING			

PRISMA 2009 Checklist

4 Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	19

Abstract:

Objectives: To systematically review and compare the efficacy of all available home-based non-pharmacological treatments of depression.

Design: Systematic review and network meta-analysis of randomized controlled trials.

Data sources: Medline, Scopus, and CINAHL databases were searched since inception to 7th August 2016.

Eligibility criteria: Randomized controlled trials comparing the efficacy of home-based non-pharmacological interventions with usual care of depressed patients were included in the review.

Main outcomes: Depression symptom scores and disease remission rates at the end of treatment.

Results: Seventeen studies were included in the review. Home-based non-pharmacological interventions were categorized as 1) home-based psychological intervention, 2) home-based exercise intervention, 3) combined home-based psychological intervention with exercise intervention, and 4) complimentary or alternative medicine. Complementary and alternative medicine approaches were excluded from the meta-analysis due to heterogeneity. The standardized mean differences of post-treatment depression symptom scores between usual care groups and home-based psychological intervention, home-based exercise intervention, and combined home-based psychological intervention with exercise intervention were -0.57 (95%CI:-0.84, -0.31), -1.03 (95%CI:-2.89, 0.82), and -0.78 (95% CI:-1.09,-0.47), respectively. These results suggest that only home-based psychological intervention and combined home-based psychological intervention with exercise intervention could significantly decrease depression scores. Compared with usual care groups, the disease remission rate was also significantly higher for home-based psychological intervention (pooled risk ratio = 1.53; 95% CI: 1.19, 1.98) and combined home-based psychological intervention with exercise intervention (pooled risk ratio = 3.47; 95% CI: 2.11, 5.70). Of all the studied interventions, combined home-based psychological intervention with exercise intervention had the highest probability of resulting in disease remission.

Conclusion: Our study confirms the efficacy of home-based psychological intervention and combined home-based psychological intervention with exercise intervention in the treatment of depression.

1
2
3 Combined home-based psychological intervention and exercise intervention was the best treatment
4 and should be considered for inclusion in clinical guidelines for managing depression.
5
6

7 **Strengths and limitations of this study**

- 9 • Our analysis provides the first comprehensive review of the efficacy of home-based non-
10 pharmacological interventions in treating depression.
11
- 12 • A comprehensive search was undertaken to identify as many relevant studies as possible.
13
- 14 • We performed a network meta-analysis to compare the efficacy of home-based interventions
15 in order to identify the best treatment regimen.
16
- 17 • The quality of included studies in the area of allocation concealment was not optimal.
18
- 19 • Participants in our included studies were aware of their own interventions and the outcomes
20 were subjective.

INTRODUCTION

Recent studies have highlighted the international recognition of depression as one of the leading global burdens of disease (GBD)¹. Depression is associated not only with greater morbidity and mortality but also with increasing health service use and costs². In addition, untreated depression has been recognized as a strong predictor of poor health outcomes in elderly³⁻⁵ and adult patients with chronic disease⁶⁻⁸.

Both pharmacological and non-pharmacological interventions, such as psychotherapy or supervised exercise intervention, have been accepted as standard treatments of depression. However, concerns about drug side effects and dependency appear to make patients prefer psychological interventions. One study showed that around 70% of depressed patients were non-compliant with antidepressants because of concerns about their side effects⁹. Even though non-pharmacological interventions were preferred over antidepressants^{10 11}, only a very small percentage of patients referred for psychotherapy were able to enter and complete this treatment¹². This inconsistency between patient preference and low rates of initiation and adherence to treatment could be a consequence of barriers to obtaining treatment. Non-pharmacological interventions are usually clinic or hospital-based and require visits on a weekly or monthly basis. In one study, 70% of patients reported structural barriers preventing them from attending psychotherapy sessions regularly and cited time constraints, transportation problems and cost as being significant obstacles¹³.

Among older patients, whose prevalent rate of depression is very high, these problems were aggravated by concurrent medical illness, social isolation, functional impairment or being home-bound¹⁴⁻²⁰. Overcoming these barriers by providing interventions in patients' own homes may achieve better treatment adherence and thereby greater treatment success than clinic or hospital-based interventions.

Home-based non-pharmacological interventions, such as problem solving therapy²¹⁻²⁵ and home-based exercise intervention^{26 27}, have developed over several years. Although some studies have suggested that these approaches can improve depressive symptoms and rates of remission when compared with standard usual care^{26 28 29}, other studies have reported conflicting results^{27 30 31}. In recent years new home-based interventions have been introduced to treat depression, such as spirituality teaching programme³² and combined home-based psychotherapy with exercise intervention but their efficacy is still controversial. Therefore, our systematic review and network meta-

1
2
3 analysis was undertaken with the aim of reviewing all available home-based non-pharmacological
4 interventions, pooling the effect sizes of each intervention on symptom improvement and indirectly
5 comparing treatment efficacy between the different interventions. The results of this review should be
6 useful for identifying the most beneficial home-based non-pharmacological interventions and for
7 informing clinical guidelines for treating depression.

12 **METHODS**

13 **Search strategy**

14
15
16
17 Relevant studies were identified using Medline, Scopus, and CINAHL databases searched
18 from inception to 7th August 2016. Reference lists of included studies were also explored. Search
19 terms and search strategies for each database are presented in a Supplementary Appendix.
20
21
22

23 **Selection of studies**

24
25
26 Initially studies were selected from titles and abstracts by two independent reviewers (K.S.
27 and T.A.). Full articles were retrieved to aid decision making if decision could not be made based on
28 titles and abstracts. Disagreement between the two reviewers was resolved by discussion.
29 Percentage agreement between the two reviewers was estimated using kappa statistics.
30
31
32
33

34 **Inclusion criteria**

35
36 Randomized-controlled trials published in English were eligible for the review if they met all of
37 the following criteria:
38
39

- 40 1. Study participants were adults aged more than 18 years with a diagnosis of any degree of
41 depressive disorder using the criteria of the Diagnostic and Statistical Manual of Mental
42 Disorders 4th Edition (DSM-IV) or any diagnostic tool used for diagnosis or screening for
43 depression. Participants who were children, adolescents or postpartum women were
44 excluded.
45
46
47
48
49
- 50 2. Interventions of interest were non-pharmacological and provided in the patient's home, such
51 as cognitive behavioral therapy, problem solving therapy, family therapy, or home-based
52 exercise intervention.
53
54
- 55 3. Treatment comparison was the standard care of depression in outpatient clinics or hospital
56 settings.
57
58
59
60

4. Outcomes were measured by the level or severity of depressive symptoms or the incidence of disease remission at the end of the intervention.
5. Studies provided sufficient data for analysis, such as number of participants (n), mean depression score, standard deviation (SD) for each intervention group, and the number of patients per intervention group with or without disease remission.

Data extraction

Two reviewers (KS and TA) independently used a standardized data record form to extract baseline characteristics of included studies and outcomes of interest. Disagreement between the two reviewers was resolved by discussion and corresponding authors of studies were contacted if information was incomplete.

Interventions of interest

Home-based non-pharmacological intervention was defined as any care or management of depression provided by health care professionals at a patient's place of residence. Home-based interventions had to have a clear and definite objective. Home visits that provided only health-education, social or emotional support were, therefore, excluded from this study.

Outcomes of interest

The outcomes of interest were depressive symptom scores and disease remission rates at the end of treatment. Disease remission was defined according to the criteria of the original article. Included studies used several tools for measuring the severity of depressive symptoms, namely the Hamilton Depression Rating Scale (HAM-D)^{21 22 30 33 34}, Patient Health Questionnaire-9 (PHQ-9)^{24 35}, Geriatric Depression Scale (GDS)^{23 26 28}, Hopkins Symptom Checklist-20 (HSCL-20)^{36 37}, Montgomery Asberg Depression Rating Scale (MADRS)^{18 25 27}, Beck Depression Inventory-Fast Screen (BDI-FS)³⁸ and Center of Epidemiologic Studies Depression Scale (CES-D)³⁹. These tools have different score ranges (HAM-D = 0-53, PHQ-9 = 0-27, GDS = 0-15, HSCL-20 = 0-4, MADRS = 0-60, BDI-FS = 0-21, and CES-D = 0-60) with higher scores in all tools representing increasing severity of depressive symptoms.

Risk of bias assessment

1
2
3 To assess the quality of included studies, a risk of bias assessment tool⁴⁰ was applied by two
4 independent reviewers (K.S., T.A.). Seven domains were evaluated as follows: 1) random sequence
5 generation 2) allocation concealment 3) blinding of participants and personnel 4) blinding of outcome
6 assessors 5) incomplete outcome data 6) selective outcome reporting 7) other sources of bias. The
7 quality of the studies was classified as being at high, unclear, or low risk of bias. We added the
8 domain of power to determine the likelihood of any studies making a true difference to outcome,
9 classifying any study as being at high risk of bias if it reported a power less than 80%. Disagreement
10 between the two reviewers was settled by discussion.
11
12
13
14
15
16
17

18 **Statistical analysis**

19
20 Because depression scores were measured differently among the studies, for direct
21 comparison the standardized mean differences (SMD) of depressive scores between intervention and
22 control groups were estimated for individual studies and then were pooled across studies.
23 Heterogeneity between studies was estimated by Q test and I^2 statistic. Heterogeneity between
24 studies was considered if the P-value from Q test was less than 0.10 or if I^2 was equal to or greater
25 than 25%⁴¹. If heterogeneity was presented, the SMD was estimated by applying the random effect
26 model. Otherwise the fixed effect model was applied.
27
28
29
30
31
32
33

34 For dichotomous outcomes, relative risks (RR) of disease remission were calculated for each
35 study. The random effect model was used for pooling RR if there was evidence of heterogeneity
36 between studies. Otherwise the inverse variance method was used. Sources of heterogeneity were
37 explored by considering possible factors one by one in a meta-regression model (e.g. mean age,
38 severity of depression at baseline and types of intervention delivery).
39
40
41
42
43

44 A network meta-analysis was applied to indirectly assess intervention effects for all home-
45 based interventions, i.e., home-based psychological intervention, home-based exercise intervention,
46 combined home-based psychological intervention and exercise intervention, and usual care. This
47 method allows us to perform indirect comparison using common comparator. For instance, some
48 studies compared home-based psychological intervention with usual care, some others compared
49 home-based exercise intervention with usual care, non or few studies compared home-based
50 psychological intervention with home-based exercise intervention. Using common comparator as
51 usual care would allow to indirectly compare home-based psychological intervention with home-based
52
53
54
55
56
57
58
59
60

1
2
3 exercise intervention⁴². Treatment effects for each study were estimated using a two-stage network
4 meta-analysis. Firstly, summary data was expanded into individual patient data using the 'expand'
5 command in STATA program. Binary regression was applied to estimate log (RR) and variance-
6 covariance of each treatment using 'mvmeta' make command. A multivariate random effect meta-
7 analysis was used to calculate the pooled RRs and their 95% confidence intervals (CI). Riley's
8 method was used for considering subject-study correlation. Treatment ranking was made according to
9 the linear predictor of each study. In addition, a consistency assumption (i.e., discrepancy of
10 intervention effects between direct and indirect meta-analyses) was assessed using the standardized
11 normal test (Z).
12
13
14
15
16
17
18
19

20 Publication bias was assessed using Egger test and funnel plot. If the funnel plot showed
21 asymmetry, a contour enhanced funnel plot was performed to explore whether asymmetry was the
22 result of heterogeneity between studies or arisen from publication bias. All analyses were performed
23 using STATA version 14. A two-sided test with P-value less than 0.05 was considered statistically
24 significant, except for the Q test, in which a P-value less than 0.10 was applied.
25
26
27
28
29

30 Patient involvement

31
32 Patients were not involved in the design of the study, development of outcome measures, or
33 conduct of the study. We did not ask patients for advice on interpreting or writing up results. There are
34 no plans to disseminate the results of the research to study participants.
35
36
37
38

39 RESULTS

40
41 We identified 385, 534, 255, and 2 articles from Medline, Scopus, CINAHL databases and
42 reference lists respectively. After deleting duplications, the titles and abstracts of 768 studies were
43 reviewed. Finally, 17 studies met our inclusion criteria and were eligible in the review (Figure 1).
44 Agreement of study selection between the two reviewers was high at 86.7% (Kappa = 0.50). All but
45 one¹⁸ of the included studies reported protocol approval by an ethics committee.
46
47
48
49
50

51 Study participants

52
53 The baseline characteristics of included studies are presented in Table 1. The type and
54 severity of depression of participants differed between studies. Four studies^{25 28 33 34} included patients
55 with major depressive disorder, four^{22 23 37 39} included patients with minor depression and nine^{18 21 24 26}
56
57
58
59
60

1
2
3 27 30 35 36 38 included patients with mixed severities of depression. Ten studies included elderly
4 patients^{18 21-26 28 37 39} while seven studies included adults with ages greater than 18 years^{27 30 33-36 38}.
5
6 Ten studies included depressed patients with other co-morbidities (i.e. epilepsy³⁶, heart diseases^{22 30}
7
8 ³⁵, disability¹⁸, and mild to moderate cognitive impairment²⁵). Twelve studies^{21 23 24 26-28 33 34 37-39}
9
10 included patients without co-morbidity. Use of anti-depressants at baseline varied widely between
11
12 studies, ranging from 0% to 95%.

14 **Home-based interventions**

15
16
17 The composition of home-based non-pharmacological interventions differed among the
18 included studies but could be categorized into 4 groups: 1) home-based psychological intervention 2)
19 home-based exercise intervention 3) combined home-based psychological intervention with home-
20 based exercise intervention 4) complementary or alternative medicine. Eight, 3 and 3 studies
21 compared home-based psychological intervention with usual care, home-based exercise intervention
22 with usual care, and combined home-based psychological intervention with home-based exercise
23 intervention with usual care, respectively. One study compared the efficacy between home-based
24 psychological intervention, home-based exercise intervention, combined home-based psychological
25 intervention with home-based exercise intervention, and usual care. Since interventions in the
26 category of complementary or alternative medicine were heterogeneous, they were not included in the
27 meta-analysis but were subjected to qualitative analysis. Details of each home-based intervention are
28 summarised below:
29
30
31
32
33
34
35
36
37
38
39

40 ***Home-based psychological intervention***

41
42 Home-based psychological intervention was classified as home-based problem-solving
43 treatment or home-based cognitive behavioral therapy.
44
45

46 1. ***Home-based problem-solving treatment*** (6 studies^{21 22 24 25 28 29})

47
48
49 Home-based problem-solving treatment (PST) is a skill-enhancing behavioral treatment of
50 depression usually delivered by social workers and psychologists. This approach assumes that
51 depressive symptoms are caused and maintained by problems of daily life and that these can be
52 reduced by identifying and addressing them systematically. Each PST session comprises 1) defining
53 and formulating the nature of the depressive problem 2) generating a range of alternative solutions to
54
55
56
57
58
59
60

1
2
3 the problem 3) systematically evaluating the possible consequences of each solution then selecting
4 the most appropriate one 4) monitoring and evaluating the actual outcome. In addition, PST identifies
5 patients' pleasurable activities and encourages them to participate in these activities.
6
7

8
9 2. *Home-based cognitive behavioral therapy (CBT)* (3 studies^{30 38 39})
10

11 The aim of CBT is to modify the dysfunctional emotions, behaviours, and thoughts of
12 depressed patients. This type of intervention was identified in 3 studies, of which 2 studies were CBT-
13 based bibliotherapy. In this approach, participants received self-help books or leaflets that included
14 instruction on cognitive behavioral self-help, mood management skills, and tasks to practice. During
15 the intervention period, participants were visited by home care nurses or contacted by telephone by
16 study investigators to assess their symptoms and encourage them to follow the course at their own
17 pace.
18
19
20
21
22
23

24
25 ***Home-based exercise intervention***
26

27 Home-based exercise intervention was employed in 4 studies. Exercise included both
28 progressive resistance training, aerobic exercise^{26 27} and aerobic exercise only^{30 34}. Participants were
29 required to perform the exercises for at least 30 minutes three times a week.
30
31
32

33
34 ***Combined home-based psychological intervention with exercise intervention***
35

36 Home-based psychological intervention combined with exercise intervention was the
37 interested intervention in 4 studies. Each of these applied aerobic exercise as a home-based exercise
38 intervention but psychological therapies differed among them (PST in two studies^{36 37}, cognitive
39 behavioral therapy in one study³⁰ and family therapy with bereavement counselling and social
40 interventions in one study¹⁸).
41
42
43
44

45
46 ***Complementary or alternative medicine***
47

48 This intervention refers to a broad set of health care practices or activities that are not
49 integrated into the dominant health care system. This type of intervention was used in 2 studies. One
50 involved home-based deep-breathing exercise³⁵ aimed at stimulating a relaxation response, (i.e. to
51 decrease arousal, heart rate and blood pressure, and to reduce responsiveness of the sympathetic
52 nervous system). Deep-breathing exercises can also help patients to disregard negative and
53
54
55
56
57
58
59
60

1
2
3 distracting thoughts. Patients were trained by experienced nurses to breathe at a rate of six breaths
4 per minute. During the treatment period, this was undertaken in a quiet environment for a period of
5 ten minutes, three times each day.
6
7

8
9 The other intervention employed a spirituality teaching programme³² aiming to promote
10 contemplation of the inter-relation between meaning and purpose, connectedness with others, nature
11 or the divine, and values such as compassion, love, justice, and forgiveness. The programme
12 comprised eight sessions involving explanation of the divine aspect of the self, teaching breathing and
13 visualization practice, helping patients to connect with the divine through prayer or meditation, letting
14 go of regret and fostering gratitude, practicing self-awareness relating to the five senses, and building
15 upon connectedness with others. Participants were also advised to avoid forming expectations and to
16 refrain from judging outcomes. Initially patients participated in a workshop run by psychiatrists and
17 were then required to practice by themselves with the help of audio CDs.
18
19
20
21
22
23
24

25 26 **Treatment comparison** 27

28
29 Usual care, defined as the standard care of depression managed in a clinic or hospital setting,
30 was applied as a treatment comparator for all studies. In addition to usual care, three studies^{25 26 29}
31 included home visits and two^{21 35} included telephone support. However, these interventions provided
32 education about depression together with general social or emotional support but did not offer specific
33 psychological help or exercise intervention. With the exception of one study³², almost all used anti-
34 depressant medication as a co-intervention but the decision to initiate or maintain this was dependent
35 on the judgement of patients and their physicians.
36
37
38
39
40
41

42 **Risk of bias assessment** 43

44
45 Results of risk of bias assessment are presented in Supplementary Table 1. Most of the
46 studies (14 studies) reported low risk of bias in the domain of random sequence generation, while 3
47 studies^{21 22 30} reported unclear risk. For allocation concealment, 11 studies^{18 21 22 25-30 38 39} had unclear
48 risk of bias, while 6 studies^{24 32 34-37} had low risk of bias. All studies reported high risk of bias in the
49 domain of blinding of participants and personnel and low risk of bias in other domains. Ten studies^{18 22}
50

57
58
59
60
25-27 29 30 32 34 36 had low risk of bias for blinding of outcome assessors, whereas 7 studies^{21 24 28 35 37-39}
had unclear risk. For the domain of incomplete outcome data, 13 studies^{18 22 24-27 29 30 32 34 36 37 39}

1
2
3 reported low risk of bias and 4 studies^{21 28 35 38} reported high risk. Almost all studies (16 studies) had
4 low risk of bias for selective outcome reporting, while only one study³⁶ had high risk of bias. In the
5 domain of power, 10 studies had unclear risk of bias, 6 reported low risk and 1 had high risk of bias.
6
7

8 9 **Pooled mean difference of depression score**

10 11 *Home-based psychological intervention vs usual care*

12
13
14 Nine studies were analyzed^{21 22 24 25 28-30 38 39} comparing home-based psychological
15 intervention with usual care (N = 739). Depression scores were assessed at the end of treatment,
16 which ranged from 6 to 48 weeks. The mean differences and 95% CIs of depression scores for each
17 study are presented in Table 2. SMD of home-based psychological intervention versus usual care
18 was -0.57 (95% CI: -0.84, -0.31), suggesting that home-based psychological intervention can
19 significantly decrease depression scores when compared with usual care.
20
21

22
23
24
25
26 Moderate heterogeneity was found between studies, with I^2 of 63.5%. Sources of
27 heterogeneity were explored but none of the factors decreased I^2 . Subgroup analyses were performed
28 according to the severity of depression (i.e. major depressive disorder (MDD), minor depression and
29 mixed severity of depression). These showed that SMDs in patients with MDD, minor depression, and
30 mixed severity of depression were -0.95 (95% CI: -1.35, -0.55; $I^2 = 16.5\%$), -0.61 (95% CI: -1.28, 0.06;
31 $I^2 = 82.1\%$), and -0.41, (95% CI: -0.62, -0.19; $I^2 = 0\%$) respectively (see Supplementary Figure 1).
32
33 These suggest that home-based psychological intervention reduces depression scores significantly in
34 the groups of MDD and mixed severity of depression. In addition, the efficacy of this intervention in
35 patients with MDD was better than the efficacy in patients with minor depression.
36
37
38
39
40
41
42

43 44 *Home-based exercise intervention vs usual care*

45
46 Three studies^{26 30 34} (N = 321) were pooled to compare the effect of home-based exercise
47 intervention with usual care. The SMD was -1.03 (95% CI: -2.89, 0.82; $I^2 = 97.9\%$) (Table 2 and
48 Supplementary Figure 2A). The mean depression score in the home-based exercise intervention
49 group was therefore 1.03 units lower than the mean depression score in the usual care group.
50
51
52
53 However, this effect did not reach statistical significance.
54
55
56
57
58
59
60

Combined home-based psychological intervention with exercise intervention vs usual care

Only two studies^{30 37} (N = 169) had sufficient data for pooling the effect on the depression score of combined home-based psychological intervention with exercise intervention. Mean depression scores were measured at the ends of the treatments, namely at 12 weeks³⁰ and 24 weeks³⁷. Table 2 shows the mean depression scores and 95% CIs for each study. SMD was -0.78 (95% CI: -1.09, -0.47; $I^2 = 0.0\%$) (Supplementary Figure 2B). This indicates that patients receiving combined home-based psychological intervention and exercise intervention had significantly lower mean depression scores (by 0.78 units) than patients receiving usual care.

Pooled risk ratio of disease remission

Home-based psychological intervention vs usual care

Four studies (N = 459) comparing the effectiveness of home-based psychological intervention with usual care had remission rates as their outcome of interest. Remission from depression was defined as HAMD score ≤ 7 in one studies²⁵, PHQ-9 ≤ 4 in one study²⁴, BDI < 4 in one study³⁸ and CES-D < 16 in one study³⁹ (Table 3). The pooled RR was 1.53 (95% CI: 1.19, 1.98) (Supplementary Figure 3), suggesting that patients receiving home-based psychological intervention were approximately 1.7 times more likely to have remission from depression than patients receiving usual care. The results among studies were homogeneous with I^2 of 0%.

Home-based exercise intervention vs usual care

Two studies (N = 248) reported their outcome as disease remission and had sufficient data for pooling. Disease remission was defined as HAMD score ≤ 7 ³⁴ or symptoms no longer meeting the criteria for major and minor depression according to DSM-IV criteria²⁷ (Table 3). The pooled RR was 0.99 (95% CI: 0.79, 1.24; $I^2 = 0.0\%$) (Supplementary Figure 4A), indicating that there was no significant difference between home-based exercise intervention and usual care in the likelihood of having remission from depression.

Combined home-based psychological intervention and exercise intervention vs usual care

Three studies (N = 279) were pooled to compare remission rates between combined psychological intervention and usual care. Disease remission was defined as HSCL-20 score < 0.5 for

1
2
3 two studies^{36 37} but in Banerjee's study¹⁸ the outcome was not clearly defined (Table 3). Pooled RR
4 was 3.47 (95% CI: 2.11, 5.70; $I^2 = 19.7\%$) suggesting that the combination of home-based
5 psychological intervention and exercise intervention significantly increased the likelihood of remission
6 from depression when compared with usual care (Supplementary Figure 4B).
7
8
9

10 **Network meta-analysis**

11 *Disease remission rate*

12
13
14
15
16 Nine studies (N = 987) were included in the network meta-analysis. Supplementary Figure 5
17 shows the network plot of home-based psychological intervention, home-based exercise intervention,
18 combined home-based psychological intervention with exercise intervention, and usual care. Size of
19 node and edge reflect the number of studies and patients respectively. From the plot, usual care was
20 the common comparator and had the largest sample size of the four treatment regimes. Home-based
21 psychological intervention versus usual care had the largest number of studies.
22
23
24
25
26

27
28 Pooled RRs for each treatment comparison are presented in Figure 2. Compared with usual
29 care, only combined home-based psychological intervention with exercise intervention and home-
30 based psychological intervention alone significantly increased the likelihood of disease remission, with
31 pooled RRs of 3.12 (95% CI: 1.71, 5.70) and 1.50 (95% CI: 1.17, 1.93) respectively. In addition, the
32 incidence of disease remission in home-based psychological intervention and combined home-based
33 psychological intervention with exercise intervention groups was significantly higher than in the home-
34 based exercise intervention group, having pooled RRs of 1.49 (95% CI: 1.07, 2.10) and 3.10 (95% CI:
35 1.63, 5.90), respectively. When compared with home-based psychological intervention alone,
36 combined home-based psychological intervention with exercise intervention also significantly
37 improved the rate of disease remission (pooled RR = 2.08; 95% CI: 1.08, 3.99).
38
39
40
41
42
43
44
45
46

47 Treatment ranking was assessed by estimating the probability of each treatment being the
48 best. This yielded probabilities of 99.5%, 0.5%, and 0% for combined home-based psychological
49 intervention with exercise intervention, home-based psychological intervention alone, and home-
50 based exercise intervention respectively. Combined home-based psychological intervention with
51 exercise intervention therefore emerged as the best intervention for achieving remission from
52 depression.
53
54
55
56
57
58
59
60

1
2
3 Applying inconsistency assumptions to the treatments, inconsistency factors were calculated
4 as 0.020 (Z=0.183, P-value=0.912) for home-based psychological intervention vs usual care, -0.018
5 (Z=0.110, P-value=0.913) for home-based exercise intervention vs usual care, and 0.106 (Z=0.107,
6 P-value=0.915) for combined home-based psychological intervention with exercise intervention
7 versus usual care. These figures find no significant difference between the direct and indirect
8 comparison of estimated treatment effects.
9

14 **Efficacy of complementary or alternative medicine**

17 Results from a study comparing the efficacy of home-based deep-breathing exercises with
18 usual care showed that patients receiving this intervention had significantly lower depression scores
19 than patients receiving usual care, with a mean difference of -1.34 (95% CI: -1.17, -0.17). Another
20 study compared the efficacy of home-based spiritual therapy with usual care. Findings from this study
21 suggested that home-based spiritual therapy could significantly decrease depression scores when
22 compared with usual care, with a mean difference of -1.11 (95% CI: -1.57, -0.65). In addition, this
23 study found that patients receiving home-based spiritual therapy were more likely to have disease
24 remission than patients receiving usual care. The risk ratio of disease remission (defined as HAMD
25 score ≤ 7) from this study was 13.85 (95% CI: 1.88, 101.74)
26
27
28
29
30
31
32
33

34 **Publication bias**

37 Egger tests and Funnel plots did not suggest any publication bias for pooling the effect of
38 home-based psychological intervention (coefficient = -0.05, P-value = 0.882) and home-based
39 exercise intervention (coefficient = 6.94, P-value = 0.818) (see Supplementary Figure 6A and 6B). For
40 combined home-based psychological intervention and exercise intervention, the Egger test did not
41 suggest publication bias but a funnel plot showed asymmetry (Supplementary Figure 7A). This
42 inconsistency might be due to Egger's test having insufficient power to detect a difference when only
43 3 studies were considered in the analysis.
44
45
46
47
48

50 The cause of this asymmetry was further explored by performing a contour enhanced funnel
51 plot which showed that most of the studies fell inside the significant area. The asymmetrical plot may,
52 therefore, result from a small study effect rather than heterogeneity between studies (see
53 Supplementary Figure 7B).
54
55
56
57
58
59
60

DISCUSSION

Our study found that a combination of home-based psychological intervention with exercise intervention and home-based psychological intervention alone both significantly decreased depressive symptoms and increased the likelihood of disease remission when compared with usual care. The SMD of home-based psychological intervention vs usual care was -0.57, which reflects the moderate magnitude of treatment effect, while SMD of combined home-based psychological intervention with exercise intervention vs usual care was -0.78 revealing the high magnitude⁴³. Treatment effect of these two interventions were comparable with selective serotonin reuptake inhibitor, which had SMD of 0.05, for treatment of depression⁴⁴. However, we could not demonstrate any benefit of home-based exercise intervention alone when compared with usual care. In addition, combined home-based psychological intervention with exercise intervention had the highest probability of remission from depression compared both with home-based psychological intervention and home-based exercise intervention.

The effectiveness of clinic-based psychological intervention for treating depression has been confirmed by previous studies^{39 45 46}. The results of our study also support the efficacy of this intervention when performed in the patient's home. In our review, the majority of participants in the included studies were depressed patients with comorbidities such as epilepsy³⁶ or heart disease^{22 30 35}, or were elderly patients with disabilities¹⁸ or cognitive impairment²⁵. These groups have a high prevalence of depression and should therefore be expected to receive a significant share of mental health provision. However, their ability to access conventional clinic-based mental health services is restricted by mobility problems and low motivation to seek help. With its ability to overcome these barriers, home-based psychological intervention is particularly appropriate in these situations.

In addition to demonstrating the efficacy of home-based psychological intervention overall, subgroup analysis within our study raises an interesting point. Home-based psychological intervention decreased symptoms of depression for all types of depression but the effect was statistically significant only in patients with MDD and mixed severity depression, not for those with minor depression. This inconsistent finding may result from the so called "ceiling" effect. The level of depressive symptoms in minor depression is relatively low at baseline when compared with major

1
2
3 depression, which could limit the potential for symptom improvement⁴⁷. This ceiling effect was also
4 found in the studies reviewing the use of antidepressant medication for minor depressive symptoms.
5
6

7 The rationale for home-based exercise intervention rests on the theory that increasing
8 physical activity can improve depressive symptoms through psychological and physiological routes.
9 Exercise serves as a distraction from worries and depressive thoughts, increases self-efficacy, and
10 gives a sense of mastery. Possible physiological mechanisms include an increase in body
11 temperature, leading to a feeling of relaxation and reduced muscle tension, an increase in levels of
12 endorphins related to positive mood and a sense of well-being, and increases in the availability of the
13 central neurotransmitters dopamine, norepinephrine and serotonin^{43,39 48}. Although the advantages of
14 clinic-based or supervised exercise to treat depression have been confirmed by previous literature¹,
15 our study found no benefit from home-based exercise intervention in ameliorating depressive
16 symptoms. The differences in these findings may be explained by poorer treatment compliance in the
17 home-based exercise intervention group, as to achieve significant benefit patients have to practice the
18 exercise programme at a prescribed intensity and frequency. Lack of motivation and inattention are
19 common symptoms in depression and may account for unsupervised patients failing to achieve the
20 prescribed levels of activity when compared with those given encouragement through supervision.
21 This assumption corresponds with findings from the home-based exercise studies^{26 27} that the
22 physical health of patients in this group (i.e. cardio-respiratory capacity, BMI, and lower limb strength),
23 the surrogate endpoints of exercise intervention, did not change significantly from baseline.
24

26
27
28
29
30
31
32
33
34
35
36
37
38

39 Although our study did not find any advantages of home-based exercise intervention over
40 usual care, when combined with psychological intervention the combined approach had a significantly
41 greater benefit than either of these interventions alone. The combination may have a synergistic
42 effect, with psychological intervention improving motivation to initiate and maintain an exercise
43 programme while the latter in turn enhances the benefits of psychological intervention.
44
45
46
47
48

49 Reviewing complimentary or alternative medicine approaches, results from Chung et al³⁵ and
50 Rickhi et al³² showed that home-based deep-breathing training and spiritual teaching programmes
51 could significantly reduce depressive symptoms when compared with usual care. However, these two
52 studies had small sample sizes and included specific populations, namely coronary heart disease
53
54
55
56
57
58
59
60

1
2
3 patients for Chung's study and middle-aged females for Rickhi's study. Their findings may not,
4
5 therefore, be generalizable to other populations.
6

7 **Strengths and limitations**

8
9
10 Our study has several strengths. Given the potential of home-based interventions to treat
11
12 depression and the increasing use of these interventions, our analysis provides the first
13
14 comprehensive review of the efficacy of home-based interventions in treating depression. A
15
16 comprehensive search was undertaken to identify as many relevant studies as possible and two
17
18 reviewers selected the studies independently with a high level of agreement. Selection bias was,
19
20 therefore less likely. In addition, we performed a network meta-analysis to compare the efficacy of all
21
22 available home-based interventions in order to identify the best treatment regime.
23

24
25 We are aware that our study may have some limitations. Firstly, the quality of included studies
26
27 in the area of allocation concealment was not optimal. The results from our study might, therefore, be
28
29 affected by selection bias and should be interpreted with caution. Secondly, participants in our
30
31 included studies were aware both of their own interventions and their subjective outcomes, including
32
33 the self-reported depression scores. However, in most of the included studies this bias from non-
34
35 blinded intervention was minimized by blinding the outcome assessors. Thirdly, some of the included
36
37 studies considered home visits as a treatment comparator. This may have resulted in an
38
39 underestimated treatment effect for the home-based interventions.
40

41
42 A network meta-analysis is a useful technique and has been increasingly applied because it
43
44 allows indirectly compare efficacy of all possible interventions given that there are some common
45
46 comparators. However, this technique is required two important assumptions, i.e., transitivity and
47
48 consistency⁴⁹. The transitivity requires that characteristics of patients and studies of those direct
49
50 comparisons that performed indirect comparisons should be similar. For instance, characteristics of
51
52 patients of home-based psychological intervention versus usual care and home-based exercise
53
54 intervention versus usual care should be similar to perform indirect comparison of home-based
55
56 psychological intervention versus home-based exercise intervention. This assumption cannot be
57
58 directly assessed and tested but consistency testing is a manifestation of transitivity. Therefore, we
59
60 assessed consistency assumption by comparing intervention effects between direct and indirect
61
62 estimates. However, numbers of included studies might play a role in this assessment, i.e., false

1
2
3 negative result might be present when direct and indirect estimates were not statistically different. For
4 our study, the inconsistency factors ranged from -0.018 to 0.106, which should be less likely to face
5 with false negative result.
6
7

8
9 We could not check consistency assumption in 3 indirect comparisons because of lack of
10 direct comparisons. We therefore explored characteristics of patients (i.e. mean age, types of
11 depression, percentage of anti-depressants use) and duration of intervention and found that they
12 mostly varied between studies and comparisons (see Supplementary Table 2). This heterogeneity
13 within and between interventions across included studies may affect the transitivity and consistency
14 assumptions of our network met-analysis. Therefore, the results from indirect comparison, e.g. the
15 efficacy of home-based psychological intervention and combined home-based psychological
16 intervention with exercise intervention over home-based exercise alone, should therefore be
17 interpreted with caution and be confirmed by undertaking further randomized-controlled trials directly
18 comparing these two interventions with home-based exercise intervention.
19
20
21
22
23
24
25
26

27 28 **Clinical implication and further study** 29

30
31 Depression is a common disorder, particularly among the elderly and in those with a chronic
32 disease. Many of these patients have difficulty accessing mental health services due to physical
33 disabilities and transportation problems. Home-based interventions to treat depression have the
34 potential to overcome these barriers and have been shown by our study to be effective. This
35 information should prove helpful when designing clinical guidelines. However, there are obvious
36 logistical differences between home-based treatments for depression and conventional clinic-based
37 care. Our study has not investigated these aspects of treatment design and, in particular, has not
38 considered manpower implications or transport costs. An economic evaluation study is needed before
39 general implementation of a home-based care model can be recommended unequivocally.
40
41
42
43
44
45
46
47

48
49 Although a randomized-controlled trial is considered to be the gold standard for therapeutic
50 research, in a real world setting this design may not be ideal for examining patient preferences and
51 adherence to treatment. In this review, most of the studies (n=10) did not report the degree of
52 adherence with the prescribed intervention. Seven studies demonstrated the effect of adherence on
53 outcomes but used different definitions to assess adherence. To maximize treatment efficacy, further
54 studies should determine the effects of patient preferences and adherence to treatment for different
55
56
57
58
59
60

1
2
3 approaches and modes of delivery as well as examine the factors that influence preferences and
4 adherence.
5
6

7 **CONCLUSION**

8
9
10 Our study has confirmed the efficacy both of home-based psychological intervention and
11 combined home-based psychological intervention with exercise intervention in decreasing symptoms
12 of depression and improving rates of remission. In addition, the combination of home-based
13 psychological intervention and exercise intervention has the highest probability of being the best
14 treatment out of all available home-based interventions. This approach should, therefore, be
15 considered when formulating clinical guidelines for treating depression.

PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	5, 6
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	-
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	6, 7
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	6
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Supplementary Appendix
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	6
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	7
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	7
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	8
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	8
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I^2) for each meta-analysis.	8

PRISMA 2009 Checklist

Page 1 of 2

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	9
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	8
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	9, Figure 1
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	9, 10, 11, 12 & Table 1
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	12 & Supplementary Table 1
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Tables 2 & 3 Figure 2 Supplementary Figure 1, 2, 3, 4
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	12-16
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	16
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	12-16
DISCUSSION			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	16-19
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	18
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	19
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	19

Abstract:

Objectives: To systematically review and compare the efficacy of all available home-based non-pharmacological treatments of depression.

Design: Systematic review and network meta-analysis of randomized controlled trials.

Data sources: Medline, Scopus, and CINAHL databases were searched since inception to 7th August 2016.

Eligibility criteria: Randomized controlled trials comparing the efficacy of home-based non-pharmacological interventions with usual care of depressed patients were included in the review.

Main outcomes: Depression symptom scores and disease remission rates at the end of treatment.

Results: Seventeen studies were included in the review. Home-based non-pharmacological interventions were categorized as 1) home-based psychological intervention, 2) home-based exercise intervention, 3) combined home-based psychological intervention with exercise intervention, and 4) complimentary or alternative medicine. Complementary and alternative medicine approaches were excluded from the meta-analysis due to heterogeneity. The standardized mean differences of post-treatment depression symptom scores between usual care groups and home-based psychological intervention, home-based exercise intervention, and combined home-based psychological intervention with exercise intervention were -0.57 (95%CI:-0.84, -0.31), -1.03 (95%CI:-2.89, 0.82), and -0.78 (95% CI:-1.09,-0.47), respectively. These results suggest that only home-based psychological intervention and combined home-based psychological intervention with exercise intervention could significantly decrease depression scores. Compared with usual care groups, the disease remission rate was also significantly higher for home-based psychological intervention (pooled risk ratio = 1.53; 95% CI: 1.19, 1.98) and combined home-based psychological intervention with exercise intervention (pooled risk ratio = 3.47; 95% CI: 2.11, 5.70). Of all the studied interventions, combined home-based psychological intervention with exercise intervention had the highest probability of resulting in disease remission.

Conclusion: Our study confirms the efficacy of home-based psychological intervention and combined home-based psychological intervention with exercise intervention in the treatment of depression.

1
2
3 Combined home-based psychological intervention and exercise intervention was the best treatment
4 and should be considered for inclusion in clinical guidelines for managing depression.
5
6

7 **Strengths and limitations of this study**

- 9 • Our analysis provides the first comprehensive review of the efficacy of home-based non-
10 pharmacological interventions in treating depression.
11
- 12 • A comprehensive search was undertaken to identify as many relevant studies as possible.
13
- 14 • We performed a network meta-analysis to compare the efficacy of home-based interventions
15 in order to identify the best treatment regimen.
16
- 17 • The quality of included studies in the area of allocation concealment was not optimal.
18
- 19 • Participants in our included studies were aware of their own interventions and the outcomes
20 were subjective.

INTRODUCTION

Recent studies have highlighted the international recognition of depression as one of the leading global burdens of disease (GBD)¹. Depression is associated not only with greater morbidity and mortality but also with increasing health service use and costs². In addition, untreated depression has been recognized as a strong predictor of poor health outcomes in elderly³⁻⁵ and adult patients with chronic disease⁶⁻⁸.

Both pharmacological and non-pharmacological interventions, such as psychotherapy or supervised exercise intervention, have been accepted as standard treatments of depression. However, concerns about drug side effects and dependency appear to make patients prefer psychological interventions. One study showed that around 70% of depressed patients were non-compliant with antidepressants because of concerns about their side effects⁹. Even though non-pharmacological interventions were preferred over antidepressants^{10 11}, only a very small percentage of patients referred for psychotherapy were able to enter and complete this treatment¹². This inconsistency between patient preference and low rates of initiation and adherence to treatment could be a consequence of barriers to obtaining treatment. Non-pharmacological interventions are usually clinic or hospital-based and require visits on a weekly or monthly basis. In one study, 70% of patients reported structural barriers preventing them from attending psychotherapy sessions regularly and cited time constraints, transportation problems and cost as being significant obstacles¹³.

Among older patients, whose prevalent rate of depression is very high, these problems were aggravated by concurrent medical illness, social isolation, functional impairment or being home-bound¹⁴⁻²⁰. Overcoming these barriers by providing interventions in patients' own homes may achieve better treatment adherence and thereby greater treatment success than clinic or hospital-based interventions.

Home-based non-pharmacological interventions, such as problem solving therapy²¹⁻²⁵ and home-based exercise intervention^{26 27}, have developed over several years. Although some studies have suggested that these approaches can improve depressive symptoms and rates of remission when compared with standard usual care^{26 28 29}, other studies have reported conflicting results^{27 30 31}. In recent years new home-based interventions have been introduced to treat depression, such as spirituality teaching programme³² and combined home-based psychotherapy with exercise intervention but their efficacy is still controversial. Therefore, our systematic review and network meta-

1
2
3 analysis was undertaken with the aim of reviewing all available home-based non-pharmacological
4 interventions, pooling the effect sizes of each intervention on symptom improvement and indirectly
5 comparing treatment efficacy between the different interventions. The results of this review should be
6 useful for identifying the most beneficial home-based non-pharmacological interventions and for
7 informing clinical guidelines for treating depression.
8

11 **METHODS**

12 **Search strategy**

13
14
15 Relevant studies were identified using Medline, Scopus, and CINAHL databases searched
16 from inception to 7th August 2016. Reference lists of included studies were also explored. Search
17 terms and search strategies for each database are presented in a Supplementary Appendix.
18
19
20
21

22 **Selection of studies**

23
24
25 Initially studies were selected from titles and abstracts by two independent reviewers (K.S.
26 and T.A.). Full articles were retrieved to aid decision making if decision could not be made based on
27 titles and abstracts. Disagreement between the two reviewers was resolved by discussion.
28 Percentage agreement between the two reviewers was estimated using kappa statistics.
29
30
31
32

33 **Inclusion criteria**

34
35
36 Randomized-controlled trials published in English were eligible for the review if they met all of
37 the following criteria:
38
39

- 40 1. Study participants were adults aged more than 18 years with a diagnosis of any degree of
41 depressive disorder using the criteria of the Diagnostic and Statistical Manual of Mental
42 Disorders 4th Edition (DSM-IV) or any diagnostic tool used for diagnosis or screening for
43 depression. Participants who were children, adolescents or postpartum women were
44 excluded.
45
46
47
48
49
- 50 2. Interventions of interest were non-pharmacological and provided in the patient's home, such
51 as cognitive behavioral therapy, problem solving therapy, family therapy, or home-based
52 exercise intervention.
53
54
- 55 3. Treatment comparison was the care of depression in outpatient clinics or hospital settings.
56
57
58
59
60

4. Outcomes were measured by the level or severity of depressive symptoms or the incidence of disease remission at the end of the intervention.
5. Studies provided sufficient data for analysis, such as number of participants (n), mean depression score, standard deviation (SD) for each intervention group, and the number of patients per intervention group with or without disease remission.

Data extraction

Two reviewers (KS and TA) independently used a standardized data record form to extract baseline characteristics of included studies and outcomes of interest. Disagreement between the two reviewers was resolved by discussion and corresponding authors of studies were contacted if information was incomplete.

Interventions of interest

Home-based non-pharmacological intervention was defined as any care or management of depression provided by health care professionals at a patient's place of residence. Home-based interventions had to have a clear and definite objective. Home visits that provided only health-education, social or emotional support were, therefore, excluded from this study.

Web or internet-based interventions were excluded from this review due to their variability in terms of content, accessibility, usability, methods of delivery and supplementary tools³³.

Outcomes of interest

The outcomes of interest were depressive symptom scores and disease remission rates at the end of treatment. Disease remission was defined according to the criteria of the original article. Included studies used several tools for measuring the severity of depressive symptoms, namely the Hamilton Depression Rating Scale (HAM-D)^{21 22 30 34 35}, Patient Health Questionnaire-9 (PHQ-9)^{24 36}, Geriatric Depression Scale (GDS)^{23 26 28}, Hopkins Symptom Checklist-20 (HSCL-20)^{37 38}, Montgomery Asberg Depression Rating Scale (MADRS)^{18 25 27}, Beck Depression Inventory-Fast Screen (BDI-FS)³⁹ and Center of Epidemiologic Studies Depression Scale (CES-D)⁴⁰. These tools have different score ranges (HAM-D = 0-53, PHQ-9 = 0-27, GDS = 0-15, HSCL-20 = 0-4, MADRS = 0-60, BDI-FS = 0-21, and CES-D = 0-60) with higher scores in all tools representing increasing severity of depressive symptoms.

Risk of bias assessment

To assess the quality of included studies, a risk of bias assessment tool⁴¹ was applied by two independent reviewers (K.S., T.A.). Seven domains were evaluated as follows: 1) random sequence generation 2) allocation concealment 3) blinding of participants and personnel 4) blinding of outcome assessors 5) incomplete outcome data 6) selective outcome reporting 7) other sources of bias. The quality of the studies was classified as being at high, unclear, or low risk of bias. We added the domain of power to determine the likelihood of any studies making a true difference to outcome, classifying any study as being at high risk of bias if it reported a power less than 80%. Disagreement between the two reviewers was settled by discussion.

Statistical analysis

Because depression scores were measured differently among the studies, for direct comparison the standardized mean differences (SMD) of depressive scores between intervention and control groups were estimated for individual studies and then were pooled across studies. Heterogeneity between studies was estimated by Q test and I^2 statistic. Heterogeneity between studies was considered if the P-value from Q test was less than 0.10 or if I^2 was equal to or greater than 25%⁴². If heterogeneity was presented, the SMD was estimated by applying the random effect model. Otherwise the fixed effect model was applied.

For dichotomous outcomes, relative risks (RR) of disease remission were calculated for each study. The random effect model was used for pooling RR if there was evidence of heterogeneity between studies. Otherwise the inverse variance method was used. Sources of heterogeneity were explored by considering possible factors one by one in a meta-regression model (e.g. mean age, severity of depression at baseline and types of intervention delivery).

A network meta-analysis was applied to indirectly assess intervention effects for all home-based interventions, i.e., home-based psychological intervention, home-based exercise intervention, combined home-based psychological intervention and exercise intervention, and usual care. This method allows us to perform indirect comparison using common comparator. For instance, some studies compared home-based psychological intervention with usual care, some others compared home-based exercise intervention with usual care, non or few studies compared home-based

1
2
3 psychological intervention with home-based exercise intervention. Using common comparator as
4 usual care would allow to indirectly compare home-based psychological intervention with home-based
5 exercise intervention⁴³. Treatment effects for each study were estimated using a two-stage network
6 meta-analysis. Firstly, summary data was expanded into individual patient data using the 'expand'
7 command in STATA program. Binary regression was applied to estimate log (RR) and variance-
8 covariance of each treatment using 'mvmeta' make command. A multivariate random effect meta-
9 analysis was used to calculate the pooled RRs and their 95% confidence intervals (CI). Riley's
10 method was used for considering subject-study correlation. Treatment ranking was made according to
11 the linear predictor of each study. In addition, a consistency assumption (i.e., discrepancy of
12 intervention effects between direct and indirect meta-analyses) was assessed using the standardized
13 normal test (Z).
14
15
16
17
18
19
20
21
22
23

24 Publication bias was assessed using Egger test and funnel plot. If the funnel plot showed
25 asymmetry, a contour enhanced funnel plot was performed to explore whether asymmetry was the
26 result of heterogeneity between studies or arisen from publication bias. All analyses were performed
27 using STATA version 14. A two-sided test with P-value less than 0.05 was considered statistically
28 significant, except for the Q test, in which a P-value less than 0.10 was applied.
29
30
31
32
33

34 Patient involvement

35
36 Patients were not involved in the design of the study, development of outcome measures, or
37 conduct of the study. We did not ask patients for advice on interpreting or writing up results. There are
38 no plans to disseminate the results of the research to study participants.
39
40
41

42 RESULTS

43
44 We identified 385, 534, 255, and 2 articles from Medline, Scopus, CINAHL databases and
45 reference lists respectively. After deleting duplications, the titles and abstracts of 768 studies were
46 reviewed. Finally, 17 studies met our inclusion criteria and were eligible in the review (Figure 1).
47 Agreement of study selection between the two reviewers was high at 86.7% (Kappa = 0.50). All but
48 one¹⁸ of the included studies reported protocol approval by an ethics committee.

Study participants

The baseline characteristics of included studies are presented in Table 1. The type and severity of depression of participants differed between studies. Four studies^{25 28 34 35} included patients with major depressive disorder, four^{22 23 38 40} included patients with minor depression and nine^{18 21 24 26 27 30 36 37 39} included patients with mixed severities of depression. Ten studies included elderly patients^{18 21-26 28 38 40} while seven studies included adults with ages greater than 18 years^{27 30 34-37 39}. Ten studies included depressed patients with other co-morbidities (i.e. epilepsy³⁷, heart diseases^{22 30 36}, disability¹⁸, and mild to moderate cognitive impairment²⁵). Twelve studies^{21 23 24 26-28 34 35 38-40} included patients without co-morbidity. Use of anti-depressants at baseline varied widely between studies, ranging from 0% to 95%.

Home-based interventions

The composition of home-based non-pharmacological interventions differed among the included studies but could be categorized into 4 groups: 1) home-based psychological intervention 2) home-based exercise intervention 3) combined home-based psychological intervention with home-based exercise intervention 4) complementary or alternative medicine. Eight, 3 and 3 studies compared home-based psychological intervention with usual care, home-based exercise intervention with usual care, and combined home-based psychological intervention with home-based exercise intervention with usual care, respectively. One study compared the efficacy between home-based psychological intervention, home-based exercise intervention, combined home-based psychological intervention with home-based exercise intervention, and usual care. Since interventions in the category of complementary or alternative medicine were heterogeneous, they were not included in the meta-analysis but were subjected to qualitative analysis. Details of each home-based intervention are summarized below:

Home-based psychological intervention

Home-based psychological intervention was classified as home-based problem-solving treatment or home-based cognitive behavioral therapy.

1. *Home-based problem-solving treatment* (6 studies^{21 22 24 25 28 29})

1
2
3 Home-based problem-solving treatment (PST) is a skill-enhancing behavioral treatment of
4 depression usually delivered by social workers and psychologists. This approach assumes that
5 depressive symptoms are caused and maintained by problems of daily life and that these can be
6 reduced by identifying and addressing them systematically. Each PST session comprises 1) defining
7 and formulating the nature of the depressive problem 2) generating a range of alternative solutions to
8 the problem 3) systematically evaluating the possible consequences of each solution then selecting
9 the most appropriate one 4) monitoring and evaluating the actual outcome. In addition, PST identifies
10 patients' pleasurable activities and encourages them to participate in these activities.
11
12
13
14
15
16
17

18 2. *Home-based cognitive behavioral therapy* (CBT) (3 studies^{30 39 40})
19

20 The aim of CBT is to modify the dysfunctional emotions, behaviours, and thoughts of
21 depressed patients. This type of intervention was identified in 3 studies, of which 2 studies were CBT-
22 based bibliotherapy. In this approach, participants received self-help books or leaflets that included
23 instruction on cognitive behavioral self-help, mood management skills, and tasks to practice. During
24 the intervention period, participants were visited by home care nurses or contacted by telephone by
25 study investigators to assess their symptoms and encourage them to follow the course at their own
26 pace.
27
28
29
30
31
32

33
34 ***Home-based exercise intervention***
35

36 Home-based exercise intervention was employed in 4 studies. Exercise included both
37 progressive resistance training, aerobic exercise^{26 27} and aerobic exercise only^{30 35}. Participants were
38 required to perform exercises of moderate-intensity for at least 30 minutes three times a week.
39
40
41
42

43 ***Combined home-based psychological intervention with exercise intervention***
44

45 Home-based psychological intervention combined with exercise intervention was the
46 interested intervention in 4 studies. Each of these applied aerobic exercise as a home-based exercise
47 intervention but psychological therapies differed among them (PST in two studies^{37 38}, cognitive
48 behavioral therapy in one study³⁰ and family therapy with bereavement counselling and social
49 interventions in one study¹⁸).
50
51
52
53
54

55 ***Complementary or alternative medicine***
56
57
58
59
60

1
2
3 This intervention refers to a broad set of health care practices or activities that are not
4 integrated into the dominant health care system. This type of intervention was used in 2 studies. One
5 involved home-based deep-breathing exercise³⁶ aimed at stimulating a relaxation response, (i.e. to
6 decrease arousal, heart rate and blood pressure, and to reduce responsiveness of the sympathetic
7 nervous system). Deep-breathing exercises can also help patients to disregard negative and
8 distracting thoughts. Patients were trained by experienced nurses to breathe at a rate of six breaths
9 per minute. During the treatment period, this was undertaken in a quiet environment for a period of
10 ten minutes, three times each day.
11
12
13
14
15
16
17

18 The other intervention employed a spirituality teaching programme³² aiming to promote
19 contemplation of the inter-relation between meaning and purpose, connectedness with others, nature
20 or the divine, and values such as compassion, love, justice, and forgiveness. The programme
21 comprised eight sessions involving explanation of the divine aspect of the self, teaching breathing and
22 visualization practice, helping patients to connect with the divine through prayer or meditation, letting
23 go of regret and fostering gratitude, practicing self-awareness relating to the five senses, and building
24 upon connectedness with others. Participants were also advised to avoid forming expectations and to
25 refrain from judging outcomes. Initially patients participated in a workshop run by psychiatrists and
26 were then required to practice by themselves with the help of audio CDs.
27
28
29
30
31
32
33
34
35

36 **Treatment comparison**

37
38 Usual care was defined as the care of depression managed by health care providers (i.e.
39 general practitioners, psychiatrists, nurses or social workers) and could include onward referral to
40 appropriate treatment services if specified in the study protocol. In addition to usual care, three
41 studies^{25 26 29} included home visits and two^{21 36} included telephone support. However, these
42 interventions provided education about depression together with general social or emotional support
43 but did not offer specific psychological help or exercise intervention. With the exception of one
44 study³², almost all used anti-depressant medication as a co-intervention but the decision to initiate or
45 maintain this was dependent on the judgments of patients and their physicians.
46
47
48
49
50
51
52

53 **Risk of bias assessment**

1
2
3 Results of risk of bias assessment are presented in Supplementary Table 1. Most of the
4 studies (14 studies) reported low risk of bias in the domain of random sequence generation, while 3
5 studies^{21 22 30} reported unclear risk. For allocation concealment, 11 studies^{18 21 22 25-30 39 40} had unclear
6 risk of bias, while 6 studies^{24 32 35-38} had low risk of bias. All studies reported high risk of bias in the
7 domain of blinding of participants and personnel and low risk of bias in other domains. Ten studies^{18,22}
8 ^{25-27 29 30 32 35 37} had low risk of bias for blinding of outcome assessors, whereas 7 studies^{21 24 28 36 38-40}
9 had unclear risk. For the domain of incomplete outcome data, 13 studies^{18 22 24-27 29 30 32 35 37 38 40}
10 reported low risk of bias and 4 studies^{21 28 36 39} reported high risk. Almost all studies (16 studies) had
11 low risk of bias for selective outcome reporting, while only one study³⁷ had high risk of bias. In the
12 domain of power, 10 studies had unclear risk of bias, 6 reported low risk and 1 had high risk of bias.
13
14
15
16
17
18
19
20
21

22 Pooled mean difference of depression score

23 *Home-based psychological intervention vs usual care*

24
25
26
27 Nine studies were analyzed^{21 22 24 25 28-30 39 40} comparing home-based psychological
28 intervention with usual care (N = 739). Depression scores were assessed at the end of treatment,
29 which ranged from 6 to 48 weeks. The mean differences and 95% CIs of depression scores for each
30 study are presented in Table 2. SMD of home-based psychological intervention versus usual care
31 was -0.57 (95% CI: -0.84, -0.31), suggesting that home-based psychological intervention can
32 significantly decrease depression scores when compared with usual care.
33
34
35
36
37
38

39 Moderate heterogeneity was found between studies, with I^2 of 63.5%. Sources of
40 heterogeneity were explored but none of the factors decreased I^2 . Subgroup analyses were performed
41 according to the severity of depression (i.e. major depressive disorder (MDD), minor depression and
42 mixed severity of depression). These showed that SMDs in patients with MDD, minor depression, and
43 mixed severity of depression were -0.95 (95% CI: -1.35, -0.55; $I^2 = 16.5\%$), -0.61 (95% CI: -1.28, 0.06;
44 $I^2 = 82.1\%$), and -0.41, (95% CI: -0.62, -0.19; $I^2 = 0\%$) respectively (see Supplementary Figure 1).
45
46
47
48
49 These suggest that home-based psychological intervention reduces depression scores significantly in
50 the groups of MDD and mixed severity of depression. In addition, the efficacy of this intervention in
51 patients with MDD was better than the efficacy in patients with minor depression.
52
53
54

55 *Home-based exercise intervention vs usual care*

1
2
3 Three studies^{26 30 35} (N = 321) were pooled to compare the effect of home-based exercise
4 intervention with usual care. The SMD was -1.03 (95% CI: -2.89, 0.82; $I^2 = 97.9\%$) (Table 2 and
5 Supplementary Figure 2A). The mean depression score in the home-based exercise intervention
6 group was therefore 1.03 units lower than the mean depression score in the usual care group.
7
8 However, this effect did not reach statistical significance.
9

10 11 12 *Combined home-based psychological intervention with exercise intervention vs usual care*

13
14
15 Only two studies^{30 38} (N = 169) had sufficient data for pooling the effect on the depression
16 score of combined home-based psychological intervention with exercise intervention. Mean
17 depression scores were measured at the ends of the treatments, namely at 12 weeks³⁰ and 24
18 weeks³⁸. Table 2 shows the mean depression scores and 95% CIs for each study. SMD was -0.78
19 (95% CI: -1.09, -0.47; $I^2 = 0.0\%$) (Supplementary Figure 2B). This indicates that patients receiving
20 combined home-based psychological intervention and exercise intervention had significantly lower
21 mean depression scores (by 0.78 units) than patients receiving usual care.
22
23
24
25
26
27

28 29 **Pooled risk ratio of disease remission**

30 31 *Home-based psychological intervention vs usual care*

32
33
34 Four studies (N = 459) comparing the effectiveness of home-based psychological intervention
35 with usual care had remission rates as their outcome of interest. Remission from depression was
36 defined as HAMD score ≤ 7 in one studies²⁵, PHQ-9 ≤ 4 in one study²⁴, BDI < 4 in one study³⁹ and
37 CES-D < 16 in one study⁴⁰ (Table 3). The pooled RR was 1.53 (95% CI: 1.19, 1.98) (Supplementary
38 Figure 3), suggesting that patients receiving home-based psychological intervention were
39 approximately 1.7 times more likely to have remission from depression than patients receiving usual
40 care. The results among studies were homogeneous with I^2 of 0%.
41
42
43
44
45
46

47 48 *Home-based exercise intervention vs usual care*

49
50 Two studies (N = 248) reported their outcome as disease remission and had sufficient data
51 for pooling. Disease remission was defined as HAMD score ≤ 7 ³⁵ or symptoms no longer meeting the
52 criteria for major and minor depression according to DSM-IV criteria²⁷ (Table 3). The pooled RR was
53 0.99 (95% CI: 0.79, 1.24; $I^2 = 0.0\%$) (Supplementary Figure 4A), indicating that there was no
54
55
56
57
58
59
60

1
2
3 significant difference between home-based exercise intervention and usual care in the likelihood of
4 having remission from depression.
5
6

7 *Combined home-based psychological intervention and exercise intervention vs usual care*

8
9
10 Three studies (N =279) were pooled to compare remission rates between combined
11 psychological intervention and usual care. Disease remission was defined as HSCL-20 score < 0.5 for
12 two studies^{37 38} but in Banerjee's study¹⁸ the outcome was not clearly defined (Table 3). Pooled RR
13 was 3.47 (95% CI: 2.11, 5.70; $I^2 = 19.7%$) suggesting that the combination of home-based
14 psychological intervention and exercise intervention significantly increased the likelihood of remission
15 from depression when compared with usual care (Supplementary Figure 4B).
16
17
18
19
20

21 **Network meta-analysis**

22 *Disease remission rate*

23
24
25
26
27
28
29

48
49
50
51
52
53
54
55
56
57
58
59
60

Nine studies (N = 987) were included in the network meta-analysis. Supplementary Figure 5 shows the network plot of home-based psychological intervention, home-based exercise intervention, combined home-based psychological intervention with exercise intervention, and usual care. Size of node and edge reflect the number of studies and patients respectively. From the plot, usual care was the common comparator and had the largest sample size of the four treatment regimes. Home-based psychological intervention versus usual care had the largest number of studies.

Pooled RRs for each treatment comparison are presented in Figure 2. Compared with usual care, only combined home-based psychological intervention with exercise intervention and home-based psychological intervention alone significantly increased the likelihood of disease remission, with pooled RRs of 3.12 (95% CI: 1.71, 5.70) and 1.50 (95% CI: 1.17, 1.93) respectively. In addition, the incidence of disease remission in home-based psychological intervention and combined home-based psychological intervention with exercise intervention groups was significantly higher than in the home-based exercise intervention group, having pooled RRs of 1.49 (95% CI: 1.07, 2.10) and 3.10 (95% CI: 1.63, 5.90), respectively. When compared with home-based psychological intervention alone, combined home-based psychological intervention with exercise intervention also significantly improved the rate of disease remission (pooled RR = 2.08; 95% CI: 1.08, 3.99).

1
2
3 Treatment ranking was assessed by estimating the probability of each treatment being the
4 best. This yielded probabilities of 99.5%, 0.5%, and 0% for combined home-based psychological
5 intervention with exercise intervention, home-based psychological intervention alone, and home-
6 based exercise intervention respectively. Combined home-based psychological intervention with
7 exercise intervention therefore emerged as the best intervention for achieving remission from
8 depression.
9

10
11
12
13
14 Applying inconsistency assumptions to the treatments, inconsistency factors were calculated
15 as 0.020 (Z=0.183, P-value=0.912) for home-based psychological intervention vs usual care, -0.018
16 (Z=0.110, P-value=0.913) for home-based exercise intervention vs usual care, and 0.106 (Z=0.107,
17 P-value=0.915) for combined home-based psychological intervention with exercise intervention
18 versus usual care. These figures find no significant difference between the direct and indirect
19 comparison of estimated treatment effects.
20
21
22
23
24

25 26 **Efficacy of complementary or alternative medicine**

27
28
29 Results from a study comparing the efficacy of home-based deep-breathing exercises with
30 usual care showed that patients receiving this intervention had significantly lower depression scores
31 than patients receiving usual care, with a mean difference of -1.34 (95% CI: -1.17, -0.17). Another
32 study compared the efficacy of home-based spiritual therapy with usual care. Findings from this study
33 suggested that home-based spiritual therapy could significantly decrease depression scores when
34 compared with usual care, with a mean difference of -1.11 (95% CI: -1.57, -0.65). In addition, this
35 study found that patients receiving home-based spiritual therapy were more likely to have disease
36 remission than patients receiving usual care. The risk ratio of disease remission (defined as HAMD
37 score \leq 7) from this study was 13.85 (95% CI: 1.88, 101.74)
38
39
40
41
42
43
44
45

46 **Publication bias**

47
48
49 Egger tests and Funnel plots did not suggest any publication bias for pooling the effect of
50 home-based psychological intervention (coefficient = -0.05, P-value = 0.882) and home-based
51 exercise intervention (coefficient = 6.94, P-value = 0.818) (see Supplementary Figure 6A and 6B). For
52 combined home-based psychological intervention and exercise intervention, the Egger test did not
53 suggest publication bias but a funnel plot showed asymmetry (Supplementary Figure 7A). This
54
55
56
57
58
59
60

1
2
3 inconsistency might be due to Egger's test having insufficient power to detect a difference when only
4
5 3 studies were considered in the analysis.
6

7
8 The cause of this asymmetry was further explored by performing a contour enhanced funnel
9
10 plot which showed that most of the studies fell inside the significant area. The asymmetrical plot may,
11
12 therefore, result from a small study effect rather than heterogeneity between studies (see
13
14 Supplementary Figure 7B).

15 **DISCUSSION**

16
17
18 Our study found that a combination of home-based psychological intervention with exercise
19
20 intervention and home-based psychological intervention alone both significantly decreased
21
22 depressive symptoms and increased the likelihood of disease remission when compared with usual
23
24 care. The SMD of home-based psychological intervention vs usual care was -0.57, which reflects the
25
26 moderate magnitude of treatment effect, while SMD of combined home-based psychological
27
28 intervention with exercise intervention vs usual care was -0.78 revealing the high magnitude⁴⁴.
29
30 Treatment effect of these two interventions were comparable with selective serotonin reuptake
31
32 inhibitor, which had SMD of 0.05, for treatment of depression⁴⁵. However, we could not demonstrate
33
34 any benefit of home-based exercise intervention alone when compared with usual care. In addition,
35
36 combined home-based psychological intervention with exercise intervention had the highest
37
38 probability of remission from depression compared both with home-based psychological intervention
39
40 and home-based exercise intervention.

41
42 The effectiveness of clinic-based psychological intervention for treating depression has been
43
44 confirmed by previous studies^{40 46}. The results of our study also support the efficacy of this
45
46 intervention when performed in the patient's home. In our review, the majority of participants in the
47
48 included studies were depressed patients with comorbidities such as epilepsy³⁷ or heart disease^{22 30}
49
50 ³⁶, or were elderly patients with disabilities¹⁸ or cognitive impairment²⁵. These groups have a high
51
52 prevalence of depression and should therefore be expected to receive a significant share of mental
53
54 health provision. However, their ability to access conventional clinic-based mental health services is
55
56 restricted by mobility problems and low motivation to seek help. With its ability to overcome these
57
58 barriers, home-based psychological intervention is particularly appropriate in these situations.
59
60

1
2
3 In addition to demonstrating the efficacy of home-based psychological intervention overall,
4 subgroup analysis within our study raises an interesting point. Home-based psychological intervention
5 decreased symptoms of depression for all types of depression but the effect was statistically
6 significant only in patients with MDD and mixed severity depression, not for those with minor
7 depression. This inconsistent finding may result from the so called “ceiling” effect. The level of
8 depressive symptoms in minor depression is relatively low at baseline when compared with major
9 depression, which could limit the potential for symptom improvement⁴⁷. This ceiling effect was also
10 found in the studies reviewing the use of antidepressant medication for minor depressive symptoms.
11
12

13
14
15
16
17
18 The rationale for home-based exercise intervention rests on the theory that increasing
19 physical activity can improve depressive symptoms through psychological and physiological routes.
20 Exercise serves as a distraction from worries and depressive thoughts, increases self-efficacy, and
21 gives a sense of mastery. Possible physiological mechanisms include an increase in body
22 temperature leading to a feeling of relaxation and reduced muscle tension, an increase in levels of
23 endorphins related to positive mood and a sense of well-being, increases in the availability of the
24 central neurotransmitters dopamine, norepinephrine and serotonin, and changes in neurobiological
25 response⁴⁸⁻⁵⁰. Although previous literature has demonstrated the benefit of supervised exercise in
26 treating depression^{51 52}, our study found no benefit from home-based exercise intervention in
27 ameliorating depressive symptoms. The differences in these findings may be explained by poorer
28 treatment compliance in the home-based exercise intervention group, as to achieve significant benefit
29 patients have to practice the exercise programme at a prescribed intensity and frequency. Lack of
30 motivation and inattention are common symptoms in depression and may account for unsupervised
31 patients failing to achieve the prescribed levels of activity when compared with those given
32 encouragement through supervision. This assumption corresponds with findings from the home-
33 based exercise studies^{26 27} that the physical health of patients in this group (i.e. cardio-respiratory
34 capacity, BMI, and lower limb strength), the surrogate endpoints of exercise intervention, did not
35 change significantly from baseline.

42
43
44
45
46
47
48
49
50

51
52 Although our study did not find any advantages of home-based exercise intervention over
53 usual care, when combined with psychological intervention the combined approach had a significantly
54 greater benefit than either of these interventions alone. The combination may have a synergistic
55
56
57
58
59
60

1
2
3 effect, with psychological intervention improving motivation to initiate and maintain an exercise
4 programme while the latter in turn enhances the benefits of psychological intervention⁵³.
5
6

7 Reviewing complimentary or alternative medicine approaches, results from Chung et al³⁶ and
8 Rickhi et al³² showed that home-based deep-breathing training and spiritual teaching programmes
9 could significantly reduce depressive symptoms when compared with usual care. However, these two
10 studies had small sample sizes and included specific populations, namely coronary heart disease
11 patients for Chung's study and middle-aged females for Rickhi's study. Their findings may not,
12 therefore, be generalizable to other populations.
13
14
15
16
17
18

19 **Strengths and limitations**

20
21 Our study has several strengths. Given the potential of home-based interventions to treat
22 depression and the increasing use of these interventions, our analysis provides the first
23 comprehensive review of the efficacy of home-based interventions in treating depression. A
24 comprehensive search was undertaken to identify as many relevant studies as possible and two
25 reviewers selected the studies independently with a high level of agreement. Selection bias was,
26 therefore less likely. In addition, we performed a network meta-analysis to compare the efficacy of all
27 available home-based interventions in order to identify the best treatment regime.
28
29
30
31
32
33
34

35 We are aware that our study may have some limitations. Firstly, the quality of included studies
36 in the area of allocation concealment was not optimal. The results from our study might, therefore, be
37 affected by selection bias and should be interpreted with caution. Secondly, participants in our
38 included studies were aware both of their own interventions and their subjective outcomes, including
39 the self-reported depression scores. However, in most of the included studies this bias from non-
40 blinded intervention was minimized by blinding the outcome assessors. Thirdly, although all studies
41 used usual care as a treatment comparator, descriptions of usual care differed among the included
42 studies (see Supplementary Table 2). For instance, usual care in Blumenthal's study consisted of
43 each participant in the control group being prescribed antidepressant medication while home-based
44 exercise participants received none. This may be responsible for a high remission rate in the control
45 group, resulting in an underestimated treatment effect for home-based exercise.

60

Network meta-analysis allows indirect comparison of the efficacy of all possible interventions, given the presence of some common comparators. However, this technique requires two important assumptions, namely transitivity and consistency⁵⁴. Transitivity requires that the characteristics of patients and studies subjected to direct and indirect comparisons should be similar. For instance, the characteristics of patients in a study comparing home-based psychological intervention with usual care and of patients in a study of home-based exercise versus usual care should be similar in order to perform an indirect comparison of home-based psychological intervention versus home-based exercise. This assumption cannot be directly assessed or tested. However, consistency testing is a manifestation of transitivity. We therefore made a consistency assumption by comparing intervention effects between direct and indirect estimates. The number of included studies may play a role in this assessment, i.e. a false negative result might be present when direct and indirect estimates are not statistically different. For our study, inconsistency factors ranged from -0.018 to 0.106, at which levels a false negative result is unlikely.

We were unable to check consistency assumption in three of the indirect comparisons due to a lack of direct comparisons. For each of these studies, we therefore explored patient characteristics (mean age and types of depression), the duration of the intervention, the percentage of antidepressant use in the intervention and control groups, and the description of usual care (see Supplementary Table 2) and found variations between studies and comparisons. For example, the definitions of usual care in the studies of combined home-based psychological intervention with exercise were not clearly defined, while the common definition of usual care in the studies into home-based psychological intervention was the standard treatment of depression by psychiatrists. This heterogeneity within and between interventions across included studies may impact both on the results and on the transitivity and consistency assumptions of our network met-analysis. Results from indirect comparison, e.g. the efficacy of home-based psychological intervention and combined home-based psychological intervention with exercise versus home-based exercise alone should therefore be interpreted with caution. Ideally, confirmation should be sought by undertaking further randomized-controlled trials directly comparing these two interventions with home-based exercise.

Clinical implication and further study

1
2
3 Depression is a common disorder, particularly among the elderly and in those with a chronic
4 disease. Many of these patients have difficulty accessing mental health services due to physical
5 disabilities and transportation problems. Home-based interventions to treat depression have the
6 potential to overcome these barriers and have been shown by our study to be effective. This
7 information should prove helpful when designing clinical guidelines. However, there are obvious
8 logistical differences between home-based treatments for depression and conventional clinic-based
9 care. Our study has not investigated these aspects of treatment design and, in particular, has not
10 considered manpower implications or transport costs. An economic evaluation study is needed before
11 general implementation of a home-based care model can be recommended unequivocally.
12
13
14
15
16
17
18
19

20 Although a randomized-controlled trial is considered to be the gold standard for therapeutic
21 research, in a real world setting this design may not be ideal for examining patient preferences and
22 adherence to treatment. In this review, most of the studies (n=10) did not report the degree of
23 adherence with the prescribed intervention. Seven studies demonstrated the effect of adherence on
24 outcomes but used different definitions to assess adherence. To maximize treatment efficacy, further
25 studies should determine the effects of patient preferences and adherence to treatment for different
26 approaches and modes of delivery as well as examine the factors that influence preferences and
27 adherence.

34

35 CONCLUSION

36
37
38 Our study has confirmed the efficacy both of home-based psychological intervention and
39 combined home-based psychological intervention with exercise intervention in decreasing symptoms
40 of depression and improving rates of remission. In addition, the combination of home-based
41 psychological intervention and exercise intervention has the highest probability of being the best
42 treatment out of all available home-based interventions. This approach should, therefore, be
43 considered when formulating clinical guidelines for treating depression.

50 **Contributors:** KS, PI, and TA were involved in the conception and design of the review. KS and TA
51 developed the search strategy, performed study selection, extracted data from included studies and
52 analyzed the data. KS, ML, PI, AD, AT and TA were involved in the interpretation and discussion of
53 results. KS and TA drafted the manuscript. PI, AD, AT and TA revised it critically for important
54 intellectual content. All authors approved the final version of the article. All authors had access to all
55
56

PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	5, 6
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	-
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	6, 7
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	6
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Supplementary Appendix
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	6
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	7
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	7
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	8
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	8
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I^2) for each meta-analysis.	8

PRISMA 2009 Checklist

Page 1 of 2

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	9
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	8
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	9, Figure 1
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	9, 10, 11, 12 & Table 1
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	12 & Supplementary Table 1
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Tables 2 & 3 Figure 2 Supplementary Figure 1, 2, 3, 4
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	12-16
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	16
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	12-16
DISCUSSION			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	16-19
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	18
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	19
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	19
