

Supplementary Information

Measured 24 h Na Excretion

Sampling and analysis methods have been described in detail previously [3]. Briefly, 68 students collected 24 h urine samples twice at an interval of 1 or 2 weeks to derive a formula for estimating 24 h Na excretion. After the first void in the morning on the first day was discarded, the student collected all voids in plastic bottles until the first void next morning. The students recorded the time of each void. The students brought 24 h urines samples in plastic bottles to their schools, and we measured total volume, took 7–8 ml of each sample in a test tube, and refrigerated it until urinalysis. The urinalysis method was the same as that employed for the overnight urine samples. The amount of 24 h sodium (24 h Na; mmol/d) excretion was calculated as follows:

$$\text{Measured Na excretion (mmol/d)} = \text{Na concentration of collected urine (mmol/L)} \times \text{urine volume of collected urine (ml)} \times 24 \text{ (h)/collection period (h)}. \quad (1)$$

Measured 24 h Na excretion was calculated using Equation (1) for each 24 h urine collection. An average of the two measurements from each person was used as an individual value. Excluding 2 subjects with incomplete questionnaire, 66 subjects were included for statistical analysis.

Table S1. Measured Na excretion ($n = 66$).
