RSMS-EX main effects: regions where RSMS-EX correlated with gray matter volumes, adjusting for age, gender, MMSE, total intracranial volume, and magnet strength. All effects shown in this table are corrected for family-wise error [FWE] across the whole brain at a significance level of p<0.05). *Affect sharing analysis:* bold text indicates regions where RSMS-EX correlated with gray matter volumes, adjusting for IRI-EC score, age, gender, MMSE, total intracranial volume, and magnet strength (FWE corrected at a significance level of P<0.05). Locations of peak coordinates are reported in MNI reference space. NS = Not significant at pFWE<0.05.

IRI-EC

RSMS-EX

RSMS-EX is represented in the top half of the table (light gray) and IRI-EC in the bottom half of the table (dark gray). The least-squares mean differences, adjusted for age, gender, and MMSE are reported with 95% confidence intervals for all patient groups that had significantly different scores on each measure ($p < 0.05$). Positive t-values indicate that the score of the patient group in the left column is greater than the corresponding patient group in the top row. Negative t-values indicate that the score of the patient group in the left column is lower than the patient group on the top row. - =not significant
