**EVALUATION OF HSP INDICATORS** 

#### Experience with the systematic evaluation and reconfirmation of a national set of health system performance indicators

**Objectives:** Evaluating an existing suite of health system performance (HSP) indicators for continued reporting using a systematic criteria-based assessment and national consensus conference.

**Design:** Modified-Delphi approach with technical and leadership groups, an online survey of stakeholders, and convening a national consensus conference.

Setting: A national health information steward, the Canadian Institute for Health Information (CIHI).

Participants: A total of 73 participants, comprised of 61 conference attendants/stakeholders from across Canada, and 12
 national health information steward staff.

Primary and secondary outcome measures: Indicator dispositions of retention, additional stakeholder consultation, further
 redevelopment, or retirement.

**Results:** Four dimensions (usability, importance, scientific soundness, and feasibility) typically used to select measures for reporting were expanded to 18 criteria grouped under the four dimensions through a process of research and testing. Definitions for each criterion were developed and piloted. Once the definitions were established, 56 of CIHI's publicly reported HSP indicators were evaluated against the criteria using modified Delphi approaches. Of the 56 HSP indicators evaluated, 9 measures were ratified for retirement, 7 were identified for additional consultation, and 3 for further research and development. A pre-Consensus Conference survey soliciting feedback from stakeholders on indicator recommendations received 48 responses (response rate of 79%). 

Conclusions: A systematic evaluation of HSP indicators informed the development of objective recommendations for
 continued reporting. The evaluation was a fruitful exercise to identify technical considerations for calculating indicators,
 furthering our understanding of how measures are used by stakeholders, as well as harmonizing actions that could be taken
 to ensure relevancy, reduce indicator chaos, and build consensus with stakeholders.

# 3435 Article summary/Strengths and limitations of this study:

- This exercise utilized an extensive suite of criteria to evaluate health system performance indicators.
- Multiple evaluation modalities were held to solicit feedback from evaluators.
- A large number of stakeholders participated in an in-person consensus conference.
- Assessment criteria and processes may not apply in other evaluation contexts.

#### BMJ Open

#### **EVALUATION OF HSP INDICATORS**

#### Introduction

2 Health indicators offer valuable insight into the performance of health systems and the health of populations. As the 3 discipline of health system performance (HSP) measurement has grown over the decades, so too have the number of 4 5 available health measures. In Europe alone, journal publications related to performance indicators increased at a rate of 6 ~20% annually between 2000 and 2009 [1]. However, the adage of more is better is not entirely true for this discipline, and 7 runs contrary to the notion of providing concise findings [2]. Health measure producers and users are constrained with 8 finite resources, and must make important decisions on which indicators they deem important, have high utility, are valid, 9 and are feasible. Periodic reviews of indicators and conceptual frameworks can ensure their continued relevance and 10 efficacy [3]. 11

12 13 Two national agencies, the Canadian Institute for Health Information (CIHI) and Statistics Canada, have collaborated for 14 more than 15 years on developing and publicly reporting health measures for health regions, provinces and territories as 15 part of the Health Information Roadmap [4]. Over the years, the number of indicators has increased from 13 in 2000 to 16 more than 80 in 2014. This in part reflects the growing information needs of health care systems in general. For example, 17 new indicators measuring outcomes, wait times, and patient safety were the areas of focus for development in recent 18 years. CIHI also expanded its indicator reporting over the years by refining the granularity of public reporting, and in 2007 19 began public reporting of health indicators for acute care hospitals in Canada. The indicators were developed and reported 20 21 on according to the CIHI–Statistics Canada Health Indicator Framework [5]. In 2012, the suite of publicly available indicators 22 at the hospital level was expanded substantially and in 2015, was expanded again to include indicators for long-term care 23 homes. 24

After a period of rapid growth in public reporting of indicators and capacity-building activities across the country, health system managers identified that having too many indicators to monitor and respond to was not achieving the goal of helping understand how well the health care system was performing. This phenomenon was termed "indicator chaos" [6], and initiated a new focus on streamlining indicator reporting and development activities.

31 Partly in response to this notion of indicator chaos, but also in efforts to ensure relevancy and efficiency, CIHI initiated a 32 program of work aimed at streamlining health system reporting in Canada. As part of this work, CIHI developed a new 33 Health System Performance Framework to better reflect the relationship between indicator measurement and health 34 system goals [5]. CIHI also recognized the need to ensure that the indicators being produced and reported reflected these 35 goals and contributed to a broader understanding of health system performance rather than continuing to add to the 36 37 reporting and monitoring burden across the country. This required a systematic indicator evaluation process that could be 38 repeated periodically to inform indicator reporting initiatives across the organization and possibly beyond. 39

Coincidentally, every five years (1999, 2004, 2009, 2014), CIHI and Statistics Canada invite stakeholders from across the
 country to a national Consensus Conference on Health Indicators to discuss priority-setting of indicator development and
 reporting for the next half decade [7,8,9,10]. The latest such conference (held in 2014) provided an opportunity to present
 the results of the internal evaluation of publicly reported indicators and to validate the results with stakeholders.

This paper describes CIHI's experience piloting the evaluation of a set of HSP indicators using a systematic criteria-based
 assessment tool and process. The results of the pilot — including achieving reconfirmation through a national consensus
 process — and possible next steps for broader implementation of the strategy are also presented in the paper.

## <u>Methods</u>

1

2

3

4 5

6

7

8

This project had four distinct components:

- 1. Process and criteria development for systematic evaluation of HSP indicators
- 2. Internal CIHI modified-Delphi sessions
- 3. Pre-conference survey of stakeholders on indicator recommendations
- 4. Presentation and ratification of results at the national Consensus Conference

#### 9 10 Systematic Evaluation of HSP Indicators

The Institute of Medicine's (IOM's) Recommendations for Measure Selection Criteria [11] — Usability, Importance, Scientific 11 Soundness and Feasibility — are consistently used in the evaluation and selection of health measures [12]. While many 12 13 examples in the literature employ these four domains of criteria, we saw the need to expand the dimensions to include 14 other criteria within three of the four domains. Through a process of research and testing, we arrived at a total of 18 criteria 15 points organized around the four IOM domains (see Table 1) that were feasible to apply and that held meaning to our 16 project objective regarding continued reporting of indicators. There is congruence between these criteria and CIHI's Data 17 Quality Framework [13] dimensions of Accuracy, Timeliness, Comparability, Usability and Relevance. Over a period of two 18 months, 56 of CIHI's suite of HSP indicators were assessed against these 18 criteria. To aid evaluators in their subsequent 19 reviews, we created a one-page summary for each indicator denoting results for each evaluation criterion [14]. 20

21

### 22 Internal CIHI modified-Delphi sessions

Two groups within CIHI participated in the evaluation. First, a technical group of experts (n=6) (comprised of

epidemiologists, methodologists and statisticians) independently reviewed each indicator and criterion point, and provided
 a Likert Scale score between 1 and 9 recommending continued reporting or otherwise (with 1 representing strong
 disagreement for continued reporting and 9 indicating strong agreement for continued reporting). Evaluators were

instructed to produce a Likert score and disposition recommendation based on a holistic assessment of all 18 criteria. We
 therefore forewent weighting evaluation criteria. This allowed for flexibility and context in instances where some criteria
 proved more informative than others.

Likert scores were averaged and presented at an internal in-person Delphi session as a basis for discussions, but were not
 automatically tied to a final result of continued indicator reporting. Beginning with the lowest average scores, each
 indicator was discussed, pertinent commentary synthesized, and a final consensus reached on a disposition
 recommendation. Disposition options for indicators were Retain, Recommend Further Research and Development (R&D) or
 Consultation, or Retire.

38

Recommendations of the technical group's Delphi sessions were then presented to the CIHI HSP leadership group (n=6)
 (comprised of senior managers and researchers) who performed a similar exercise. First, they were asked to independently

41 (comprised of senior managers and researchers) who performed a similar exercise. First, they were asked to independently
 42 review all results to date (including indicator assessments and Likert scores, commentary and disposition
 43 recommendations). Results of their individual assessments were collated and presented at an in-person session. Disposition

recommendations): Results of their individual assessments were conated and presented at an in-person session. Disposition
 recommendations for each of the 56 indicators were solidified. The RAND/UCLA Appropriateness Method [15] guided our
 internal iterative modified-Delphi sessions.

46

#### 47 48 Pre-conference survey of stakeholders on indicator recommendations

A pre-Consensus Conference survey solicited initial feedback on recommendations. The online survey was available for a
 period of six weeks prior to the conference. Consensus Conference participants were chosen from an existing list of CIHI
 partners, stakeholders, and clients; common roles of participants were hospital/health region CEOs, academics and
 researchers, representatives from ministries of health, clinicians, and national collaboration partners. An electronic survey
 was emailed to conference participants along with background documentation on the evaluation process, methodology,
 and recommendations. The survey asked respondents whether they Agreed, Disagreed or had No Opinion on the
 recommendation to retire select HSP indicators as per recommendations from CIHI's internal review.

28

# 2 <u>Systematic evaluation of HSP indicators</u>

3 Systematic evaluation of HSP indicators
 4 The systematic evaluation of HSP indicators was a holistic process considering 18 criteria points. Some criteria differentiated
 5 indicators more than others. For example, a small number of criteria resulted in mostly uniform findings for the suite of HSP
 6 indicators. However, when assessed alongside remaining criteria, important contextual considerations can be gleaned.
 7 Notable findings are summarized below by criterion.

#### 9 Usability

Dsability
 The Granularity of reporting criterion identified nuances inherent within public reporting purposes. There are approxiametly
 100 administrative health regions in Canada, and approxiametely 600 acute care hospitals. Twenty-nine indicators are
 reported at the regional level, and 27 are reported at the hospital/facility level. All indicators are reported at an aggregate
 provincial/territorial and national level.

With respect to *Pan-Canadian coverage*, 44 of 56 indicators provided complete pan-Canadian coverage (all provinces and territories). The province of Quebec does not have available or comparable data for a dozen indicators. Similar to the criterion of pan-Canadian coverage, the *Comprehensiveness* criterion assessed the inclusiveness of health services providers that submit data toward the indicator. For example, the mental illness hospitalization indicator includes data on mental health patients treated in general hospitals only, while hospitalizations at free-standing psychiatric institutions are not included due to the differences in data collection.

For the *Usage* criterion, we polled CIHI HSP staff responsible for interacting with clients on indicators and data requests. This provided a proxy for the level and extent of the indicator's usage by clients. The 56 indicators under evaluation were rated as High (n=33), Medium (n=15) or Low usage (n=8).

With regard to *Dimensionality*, breakdowns of indicator results by dimensions of sex and socio-economic status (SES) are available where applicable. Thus, 15 indicators are reportable by SES and 14 are reportable by sex.

In terms of *Timeliness, Reporting frequency and Accessibility,* all 56 indicators were publicly reported annually within 10
 months of the relavent data being available for analysis. At the time of the evaluation, all HSP indicators were accessible
 publicly through online publications such as the Health Indicators e-Publication. Additionally, a majority of facility-level
 indicators are available to providers through private online tools to allow for more granular breakdowns of results and peer
 comparative reports.

For the *Trendability* criterion, it was found that time trends vary by indicator. For example, the set of facility-level indicators was largely first reported beginning with 2007 data. Results for select regional indicators dated back to 1997. Overall, regional indicators possessed almost twice as many available years of results compared with facility indicators, a nature of the timing of reporting programs.

#### 45 <u>Importance</u>

As a proxy measure for *Relevance*, an environmental scan was conducted to understand stakeholder utilization of
 indicators. A total of 232 instances online were recorded. The top five indicators were Hospital Standardized Mortality Ratio
 (HSMR) (n=23), 30-Day Overall Readmission (n=18), Wait Times for Hip Fracture Repair (n=17), Ambulatory Care Sensitive
 Conditions (n=14), and Caesarean Section Rate (n=13).

52 Detailed statements on the *Actionability* of each indicator were provided to evaluation participants. Specifically, 53 summations on the purpose of indicator, strengths, caveats, and scientific evidence in support were considered. 54

To measure the degree of *Stakeholder follow-up*, we reviewed all instances of patient-level data requests from providers. In 2013-14, there were 298 requests, with 11 facility-level readmission indicators accounting for 58% of all requests (n=173).

58

51

44

Page 7 of 17

#### BMJ Open

#### **EVALUATION OF HSP INDICATORS**

1 The criterion Sufficient volumes quantifies the proportion of indicator results that are suppressed per CIHI's data privacy 2 protocols. In general, indicator results with cell counts less than five are suppressed, and results based on less than 50 3 denominator cases per hospital are flagged as low volume and unstable rates. Facility-level indicators are particularly 4 5 affected by low volumes and suppressed results: 23 of 27 facility-level indicators had at least one-fifth of all results flagged 6 as low volume. A further 7 of these indicators had at least one-fifth of all results suppressed due to small cell counts. At the 7 extreme, we note the 28-Day Readmission After Stroke and Acute Myocardial Infarction (AMI) indicators with ~75% low 8 volume rates and one-third of all results suppressed. 9

We performed *Significance of variation* analysis to determine the variability within indicator results. For example, the Hip
 Fracture Surgical Procedures Performed Within 48 Hours indicators (both Within One and Across facilities) had the lowest
 relative standard deviation values of 16% and 17%, respectively, indicating minimal differences across indicator results.

#### 15 <u>Scientific Soundness</u>

The criterion *Data quality* garnered the greatest discussion during Delphi reviews. Limitations of using administrative data were considered. Examples of concern include the inability to assess indications for angiography for AMI patients for the indicator Use of Coronary Angiography Following AMI, and the ability to properly identify denominator cases for the Hysterectomy indicator.

The evaluation revealed that *Validity reviews* were performed for each indicator on an annual basis. These included significance testing of risk factors, monitoring of diagnosis and procedure coding updates, and outlier and significant change analyses. Indicators recommended for further consultation and R&D were identified as such mainly for the purpose of seeking feedback from stakeholders on the validity and clinical relevance of current calculation methodologies.

27

21

The criterion *Participation bias* assessed whether data submission and participation in the calculation of indicator results were a nature of voluntary participation. All but two indicators — Physician Specialists and General/Family Physicians per 100,000 Population — required mandatory participation. In other instances, such as indicators produced for long-term care facilities, participation is not yet mandatory across the country, and therefore results published may contain a participation bias.

34 35 <u>Feasibility</u>

36 Production cost was considered based on the extent of staff resources required to produce each indicator. Indicators with 37 complex linkages across multiple databases and those requiring building of episodes of care necessitate a larger degree of 38 resources. 39

40 . . .

## 40 Modified-Delphi sessions of CIHI technical and leadership groups

Mean Likert scores, recommendations and rationale are noted in tables 2, 3 and 4. Nine indicators were recommended as candidates for retirement (Table 3), seven were identified as requiring additional consultation and three were

recommended to undergo further redevelopment (Table 2). Thirty-five indicators were recommended for retention (Table
 4). The rationale to retain these HSP indicators was based on holistic decisions across 18 criteria points. Although retained
 indicators correlate strongly with high mean Likert scores, this was only one contributor to the recommendation.

47

CIHI leadership and technical groups identified indicators for additional consultation and redevelopment. These indicator
 recommendations were not forwarded to Consensus Conference participants, but were instead identified for internal R&D
 efforts in the interim.

52

## 53 Pre-Consensus Conference survey

Forty-eight Consensus Conference participants completed the online survey (response rate of 79%). Eighty-five percent of conference participants had more than 10 years of health care experience. Geographic distribution of respondents correlated well with Canada's population across provinces/territories. The mean survey agreement score (as a percentage of responses) for all nine indicators proposed for retirement was 70%, and was used as a benchmark for automatic

59 ratification.

#### National Consensus Conference

#### **EVALUATION OF HSP INDICATORS**

Of the nine indicators recommended for retirement, six received more than 70% agreement as a proportion of responses in the pre-conference survey, and therefore were automatically accepted for retirement (Table 3). The remaining three indicators were discussed as a group, and subsequently also ratified for retirement by conference participants. The majority of indicators recommended for retirement were condition-specific readmission indicators. Ultimately, the decision to retire

these indicators was based on appropriateness for continued public reporting. While these indicators were ratified for retirement over concerns of rate stability and small numbers, facilities can continue to calculate and monitor these indicators through CIHI private reporting tools. Consensus on retiring these indicators was achieved with greater ease given that a provider's capacity to continue to privately monitor performance would be maintained.

Two contextual health human resources indicators at the regional level — Physician Specialists and General/Family Physicians per 100,000 Population — were also included in the modified Delphi review process, and rated low in Likert Scale scoring (both received a mean score of 3.2). While these indicators provide some context on HSP characteristics, they are already reported elsewhere within CIHI. It was agreed to continue reporting on these indicators but outside of the HSP framework. 

Table 4 lists 35 HSP indicators retained for continued public reporting. Although retained indicators correlate strongly with high mean Likert scores, this was only one contributor to the recommendation. For example, the regional level Caesarean Section Rate indicator received a mean Likert score of 4.8 from the technical group, but was retained for public reporting after discussion by the leadership group due to continued concerns over high rates in Canada and therefore a need for continued monitoring.

#### **EVALUATION OF HSP INDICATORS**

#### **Discussion**

This exercise proved to be an informative, objective, systematic, transparent, inclusive, and likely repeatable process for evaluating and reconfirming a national set of HSP indicators. Overall, the approach of using 18 sub-criteria was manageable and informative, with feedback from participants that the added information and context made it easier to make a final disposition recommendation for each indicator. The overall timeline of the evaluation process from inception to completion was 18 months. Three distinct phases stand out, each requiring approximately six months to complete: initial R&D of the evaluation plan, executing the evaluation internally at CIHI, and achieving consensus across stakeholders.

8 9 10

1

2

3

4

5 6

7

An initial Likert score of indicators provides a baseline to proceed with group Delphi reviews. We found it beneficial to begin with the lowest scores and work our way to the highest rated indicators. We also found it operational to have our technical group first review indicators and to pass on recommendations to a leadership group that would consider these in addition to their knowledge and understanding of the use of HSP information in the field. The iterative process of having participants first review indicators independent of other Delphi members and to then convene as a group to discuss findings allowed for a balanced and participatory discussion among participants. These iterative methods ensured a summative process whereby findings were transparent and confirmed at each stage.

#### 10 19

The national Consensus Conference provided an opportunity to pilot-test the results of a rigorous, mostly internal methodology for evaluating indicators produced by CIHI. While stakeholders appreciated the opportunity to review and ratify our findings, stakeholders indicated that, going forward, they were comfortable with CIHI implementing a systematic evaluation of the indicators and making decisions about reporting. There was congruence in opinion on the suitability of HSP indicators for public reporting throughout the evaluation process, beginning with Likert scores and assessments from CIHI technical staff, to CIHI leadership, and lastly with stakeholders.

27

37

#### 28 Strengths and weaknesses of the study

While the overall evaluation required considerable time and resources, there are important benefits to such a comprehensive process. We ensured a transparent and sequential evaluation, whereby discourse and findings were accumulated and presented in a summarized manner at each phase. We solicited feedback from evaluators both independently and in a group manner (also polling online and in-person at the consensus conference). An external moderator facilitating discussion can ensure independence during the consensus process. The aforementioned processes have been described as favourable conceptual approaches to aid exercises of indicator development, maintenance, and evaluation [14].

38 Shekelle [16] notes there is little agreement on methodologies for developing performance indicators, and this can be said 39 of the same regarding their evaluation. Nonetheless, Stelfox and Straus [14] emphasize the importance of clearly 40 establishing the chosen evaluation criteria in advance of launching a consensus process. In the majority of the studies we 41 reviewed and cite, a smaller number of evaluation criteria were applied: most often, usability, importance, scientific 42 soundness, and feasibility (or a variation thereof that drew upon similar domains). Conversely, we found it helpful to apply 43 44 multiple sub-criteria to comprehensively reflect the evaluation of indicators for their suitability of ongoing public reporting. 45 Furthermore, providing a more granular evaluation schema for participants ensured more consistent definitions of domains 46 and structured evidence/results for evaluators' consideration. Nonetheless, while these evaluation criteria were informative 47 and applicable to this precise context, not all would apply for other evaluation purposes. Further efforts are necessary to 48 determine the level of customization required to ensure that the process and criteria are applicable to other sectors of care 49 and types of indicators. 50

51

52 In addition to convening an in-person consensus conference (or expert panel) to evaluate indicators, Santana et al [17] 53 forwarded their evaluation survey to 101 trauma centres across four countries involved in the use and assessment of injury-54 care indicators. Moreover, a novel subsequent processes has been described by Bobrovitz et al [18] whereby the discussion 55 occurring throughout the consensus conference is transcribed and undergoes qualitative content analysis to identify key 56 themes raised throughout the deliberations. These additional activities can provide complementary evidence to the 57 evaluation process, such as qualitative findings to an otherwise objective and quantitative exercise, and reaching a broader 58 59 group of stakeholders and users of health measures. 60

**EVALUATION OF HSP INDICATORS** 

BMJ Open

#### <u>Conclusion</u>

# The proliferation of health measures required to fulfill reporting gaps occurred with minimal consideration to alignment and utility with pre-existing indicators. Not surprisingly, then, stakeholders were overwhelmingly in favour of implementing a process that would result in a leaner, more applicable suite of HSP indicators.

CIHI will gradually expand this evaluation methodology to applicable sectors of care. We will also continue to work with external partners to reduce indicator chaos and increase alignment with reporting requirements across the country [6].

This exercise generated identified analytical alignment actions that can be taken at CIHI throughout indicator production
 and maintenance with a view to reduce indicator chaos. Furthermore, we gained new knowledge about how the HSP
 indicators we produce are used by stakeholders both through an internet-based environmental scan and via discussions
 held at the Consensus Conference [10].

In line with established practices of convening a Consensus Conference every five years, we feel that it is highly beneficial to inform those discussions with a wholesale and systematic criteria-based review of indicators just prior. A broad consultation process encompassing diverse public health stakeholders from across the country helps ensure the development and use of indicators most appropriately reflecting the health of populations and the performance of health systems [19]. Similarly, a retrospective exercise on national HSP practices can identify important lessons, of which the selection of indicators suitable for public reporting is an integral component [20].

Domain/Criterion	Definition
<u>sability</u>	
• Granularity of reporting	Reporting at national, provincial/territorial, regional and facility levels
• Pan-Canadian coverage	Extent of participation from all provinces and territories
· Comprehensiveness	Proportion of providers submitting data for the indicator
· Usage	Level and extent of usage
· Dimensionality	Ability to break down results by age, sex, socio-economic status, and other dimensions
· Timeliness	Latest year of available results
· Reporting frequency	Whether indicator is reported quarterly, annually or other
· Accessibility	Whether the indicator is publicly and/or privately reported
· Trendability	Number of years of available results for trending
nportance_	
· Relevance	Environmental scan identified uses of indicator by stakeholders
· Actionability	Extent to which providers can meaningfully influence the indicator
· Stakeholder follow-up	Number of data and methodological requests within last fiscal year
Sufficient volumes	Percentage of results suppressed (due to low counts)
· Significance of variation	Degree of variation across reported values
cientific Soundness	
· Data quality	Strength of data quality, ability to validate results, based on standard
· Validity review	Extent and frequency of reviewing indicator's validity/methodology
· Participation bias	Mandatory or voluntary participation by providers
easibility	
Production cost	Extent of staff/resources to produce indicator

Туре	Indicator	Mean Likert Score	Rationale
Decien	Llin Donlocoment		
Region	Hip Replacement	5.0	
	Knee Replacement	4.8	There are concerns of utility and actionability for these
	Coronary Artery Bypass Graft (CABG)	6.6	There are concerns of utility and actionability for these indicators as they represent procedure counts per
	Percutaneous Coronary Intervention (PCI)	6.6	population.
	Cardiac Revascularization	6.6	
Facility	Vaginal Birth After Caesarean Section	4.4	There are concerns of validity and utility for these indicators.
	Birth Trauma	5.4	
		FURTHER F	REDEVELOPMENT
Region	Hysterectomy	4.4	R&D is required to improve identification of appropriate denominator cases.
Facility	Nursing Sensitive Adverse Events for Medical Patients	6.8	There is an opportunity for incorporation within newly
	Nursing Sensitive Adverse Events for Surgical Patients	6.8	- developed Hospital Harm indicator.

T y p e	Indicator	Mean Likert Score	Rationale	Pre–Consensus Conference Survey Agreement (as a % of responses)
	28-Day Readmission After Prostatectomy	5.2	These indicators have low volumes of cases leading to unstable rates as well as to the suppression of a large	82%*
	28-Day Readmission After Hysterectomy	5.6	number of results for public reporting. Furthermore, these cases are included in the Surgical/Medical Readmission	80%*
	90-Day Readmission After Knee Replacement	6.4	indicators, and can still be derived through private reporting tools.	73%*
	90-Day Readmission After Hip Replacement	6.4		72%*
	28-Day Readmission After Stroke	6.2		58%
	Use of Coronary Angiography Following AMI	6.4	Angiography may not be indicated for every AMI patient, depending on his or her clinical history, and the clinical appropriateness of angiography is difficult to ascertain from the administrative hospitalization data. Therefore, it is challenging to interpret and compare the results for this indicator.	78%*
Facility	Hip Fracture Surgical Procedures Performed Within One Facility (48 Hours)	6.4	This indicator does not measure the true proportion of surgeries performed within 48 hours of admission to an acute care hospital, since it does not account for transfers across hospitals. Many patients are transferred from their initial admitting acute care facility to another facility for surgery. The indicator Hip Fracture Surgical Procedures Performed Within 48 Hours, which measures total time across all acute care facilities, will continue to be produced and reported on.	72%*
	28-Day Readmission After AMI	6.4	Concerns have been raised regarding hospitals' ability to take action on this indicator. It is felt that with the regionalization of cardiac care, it is more appropriate to measure readmission after AMI at the regional level (by patient residence) than at the hospital level. In addition, having a low volume of cases leads to unstable rates and to the suppression of a large number of results for public reporting. Therefore, it was proposed to keep the Readmission After AMI indicator at the regional level and to retire the facility-level indicator. Furthermore, readmissions after AMI are included in the 30-Day Overall Readmission indicator at the facility level.	59%
	Primary Caesarean Section Rate	4.6	A new indicator (Low-Risk Caesarean Section) measures the rate of deliveries via Caesarean section among singleton term cephalic pregnancies for women without placenta previa or previous C-section. Since this new indicator is limited to women who have not had a previous C-section, it can take the place of Primary Caesarean Section Rate and be a better indicator of appropriateness.	57%

#### **EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS**

A systematic approach to evaluating and confirming the utility of a suite of national health system performance (HSP) indicators in Canada: a modified Delphi study

**Objectives:** Evaluating an existing suite of health system performance (HSP) indicators for continued reporting using a systematic criteria-based assessment and national consensus conference.

**Design:** Modified-Delphi approach with technical and leadership groups, an online survey of stakeholders, and convening a national consensus conference.

Setting: A national health information steward, the Canadian Institute for Health Information (CIHI).

**Participants:** A total of 73 participants, comprised of 61 conference attendants/stakeholders from across Canada, and 12 national health information steward staff.

**Primary and secondary outcome measures:** Indicator dispositions of retention, additional stakeholder consultation, further redevelopment, or retirement.

Results: Four dimensions (usability, importance, scientific soundness, and feasibility) typically used to select measures for
 reporting were expanded to 18 criteria grouped under the four dimensions through a process of research and testing.
 Definitions for each criterion were developed and piloted. Once the definitions were established, 56 of CIHI's publicly
 reported HSP indicators were evaluated against the criteria using modified Delphi approaches. Of the 56 HSP indicators
 evaluated, 9 measures were ratified for retirement, 7 were identified for additional consultation, and 3 for further research
 and development. A pre–Consensus Conference survey soliciting feedback from stakeholders on indicator
 recommendations received 48 responses (response rate of 79%).

# Conclusions: A systematic evaluation of HSP indicators informed the development of objective recommendations for continued reporting. The evaluation was a fruitful exercise to identify technical considerations for calculating indicators, furthering our understanding of how measures are used by stakeholders, as well as harmonizing actions that could be taken to ensure relevancy, reduce indicator chaos, and build consensus with stakeholders.

#### 6 Article summary/Strengths and limitations of this study:

- This exercise utilized an extensive suite of criteria to evaluate health system performance indicators.
- Multiple evaluation modalities were used to solicit feedback from evaluators.
- A large number of stakeholders participated in an in-person consensus conference.
- Assessment criteria and processes may not apply in other evaluation contexts.

#### **EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS**

# 1 <u>Introduction</u>

2 Health indicators offer valuable insight into the performance of health systems and the health of populations. As the 3 discipline of health system performance (HSP) measurement has grown over the decades, so too have the number of 4 5 available health measures. In Europe alone, journal publications related to performance indicators increased at a rate of 6 ~20% annually between 2000 and 2009 [1]. However, continuing to increase the number of indicators reported runs 7 contrary to, and inhibits, the provision of concise findings on the performance of health systems [2]. Health measure 8 producers and users are constrained with finite resources, and must make important decisions on which indicators they 9 deem important, have high utility, are valid, and are feasible. Periodic reviews of indicators and conceptual frameworks can 10 ensure their continued relevance and efficacy [3]. 11

12 13 Two national agencies, the Canadian Institute for Health Information (CIHI) and Statistics Canada, have collaborated for 14 more than 15 years on developing and publicly reporting health measures for health regions, provinces and territories as 15 part of the Health Information Roadmap [4]. Over the years, the number of indicators has increased from 13 in 2000 to 16 more than 80 in 2014. This in part reflects the growing information needs of health care systems in general. For example, 17 new indicators measuring outcomes, wait times, and patient safety were the areas of focus for development in recent 18 years. CIHI also expanded its indicator reporting over the years by refining the granularity of public reporting, and in 2007 19 began public reporting of health indicators for acute care hospitals in Canada. The indicators were developed and reported 20 21 on according to the CIHI–Statistics Canada Health Indicator Framework [5]. In 2012, the suite of publicly available indicators 22 at the hospital level was expanded substantially and in 2015, was expanded again to include indicators for long-term care 23 homes. 24

After a period of rapid growth in public reporting of indicators likely due to the rising demand for accountability and quality improvement data as well as increases in capacity-building activities across the country, health system managers identified that having too many indicators to monitor and respond to was not achieving the goal of helping understand how well the health care system was performing. In 2010, this phenomenon was coined "indicator chaos" [6], and initiated a new focus on streamlining indicator reporting and development activities.

32 Partly in response to this notion of indicator chaos, but also in efforts to ensure relevancy and efficiency, CIHI initiated a 33 program of work aimed at streamlining health system reporting in Canada. As part of this work, CIHI developed a new 34 Health System Performance Framework to better reflect the relationship between indicator measurement and health 35 system goals [5]. CIHI also recognized the need to ensure that the indicators being produced and reported reflected these 36 37 goals and contributed to a broader understanding of health system performance rather than continuing to add to the 38 reporting and monitoring burden across the country. This required a systematic indicator evaluation process that could be 39 repeated periodically to inform indicator reporting initiatives across the organization and possibly beyond. 40

Coincidentally, every five years (1999, 2004, 2009, 2014), CIHI and Statistics Canada invite stakeholders from across the
 country to a national Consensus Conference on Health Indicators to discuss priority-setting of indicator development and
 reporting for the next half decade [7,8,9,10]. The latest such conference (held in 2014) provided an opportunity to present
 the results of the internal evaluation of publicly reported indicators and to validate the results with stakeholders.

This paper describes CIHI's approach to evaluating of a set of HSP indicators using a systematic criteria-based assessment
 tool and process. The results of the pilot — including achieving reconfirmation through a national consensus process — and
 possible next steps for broader implementation of the strategy are also presented in the paper.

#### EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS

#### <u>Methods</u>

1

2

3

4 5

6

7

8

This project had four distinct components:

- 1. Process and criteria development for systematic evaluation of HSP indicators
- 2. Internal CIHI modified-Delphi sessions
- 3. Pre-conference survey of stakeholders on indicator recommendations
- 4. Presentation and ratification of results at the national Consensus Conference

#### 9 10 Systematic Evaluation of HSP Indicators

The Institute of Medicine's (IOM's) Recommendations for Measure Selection Criteria [11] — Usability, Importance, Scientific 11 Soundness and Feasibility — are consistently used in the evaluation and selection of health measures [12]. While many 12 13 examples in the literature employ these four domains of criteria, we saw the need to expand the dimensions to include 14 other criteria within three of the four domains. Through a process of research and testing, we arrived at a total of 18 criteria 15 points organized around the four IOM domains (see Table 1) that were feasible to apply and that held meaning to our 16 project objective regarding continued reporting of indicators. There is congruence between these criteria and CIHI's Data 17 Quality Framework [13] dimensions of Accuracy, Timeliness, Comparability, Usability and Relevance. Over a period of two 18 months, 56 of CIHI's suite of HSP indicators were assessed against these 18 criteria. To aid evaluators in their subsequent 19 reviews, we created a one-page summary for each indicator denoting results for each evaluation criterion [14]. 20

21

#### 22 Internal CIHI modified-Delphi sessions

<sup>23</sup> Two groups within CIHI participated in the evaluation. First, a technical group of experts (n=6) (comprised of

epidemiologists, methodologists and statisticians) independently reviewed each indicator and criterion point, and provided
 a Likert Scale score between 1 and 9. Likert scores were assessed as follows: 7-9 was considered as robust strength for the

- indicator and agreement for continued reporting; 4-6 denoted equivocal evidence and further discussion at in-person
  Delphi session is required; and, 1-3 was considered as weak support for the indicator suggesting it should be retired.
- Respondents were instructed to produce a Likert score and disposition recommendation based on their assessment of all 18 evaluation criteria as a whole. We therefore forewent weighting evaluation criteria. This allowed for flexibility and context in instances where some criteria proved more informative than others.
- Likert scores were averaged and presented at an internal in-person Delphi session as a basis for discussions, but were not automatically tied to a final result of continued indicator reporting. The mean was used to average scores as there were no outlier values across responses. Furthermore, all individual respondent ratings were shown alongside the mean score, thereby illustrating the level of concordance. Beginning with the lowest average scores, each indicator was discussed, pertinent commentary synthesized, and a final consensus reached on a disposition recommendation. Disposition options for indicators were Retain, Recommend Further Research and Development (R&D) or Consultation, or Retire.
- 40 41

Recommendations of the technical group's Delphi sessions were then presented to the CIHI HSP leadership group (n=6)
 (comprised of senior managers and researchers) who repeated the preceding exercise. First, they were asked to
 independently review all results to date (including indicator assessments and Likert scores, commentary and disposition
 recommendations). Results of their individual assessments were collated and presented at an in-person session. Disposition
 recommendations for each of the 56 indicators were consolidated and finalized based on group consensus. The RAND/UCLA
 Appropriateness Method [15] guided our internal iterative modified-Delphi sessions.

40 49

#### 50 <u>Pre-conference survey of stakeholders on indicator recommendations</u>

A pre-Consensus Conference survey solicited initial feedback on recommendations. The online survey was available for a 51 52 period of six weeks prior to the conference. Consensus Conference participants were chosen from an existing list of CIHI 53 partners, stakeholders, and clients; participants were largely hospital/health region CEOs, academics and researchers, 54 representatives from ministries of health, clinicians, and national collaboration partners involved in measuring and 55 monitoring the performance of the health care system. An electronic survey was emailed to conference participants along 56 with background documentation on the evaluation process, methodology, and recommendations. The survey asked 57 respondents whether they Agreed, Disagreed or had No Opinion on the recommendation to retire select HSP indicators as 58 59 per recommendations from CIHI's internal review. 60

28

# 2 <u>Systematic evaluation of HSP indicators</u>

3 Systematic evaluation of HSP indicators
 4 The systematic evaluation of HSP indicators was a summative process considering 18 criteria points. Some criteria
 5 differentiated indicators more than others. For example, a small number of criteria resulted in mostly uniform findings for
 6 the suite of HSP indicators. However, when assessed alongside remaining criteria, important contextual considerations can
 7 be gleaned. Notable findings are summarized below by criterion.

# 7 be gleaned. Notable findings are summarized below by criterion.

#### 9 10 <u>Usability</u>

The *Granularity of reporting* criterion identified nuances inherent within public reporting purposes. There are approxiametly 100 administrative health regions in Canada, and approxiametely 600 acute care hospitals. Twenty-nine indicators are reported at the regional level, and 27 are reported at the hospital/facility level. All indicators are reported at an aggregate provincial/territorial and national level.

With respect to *Pan-Canadian coverage*, 44 of 56 indicators provided complete pan-Canadian coverage (all provinces and territories). The province of Quebec does not have available or comparable data for a dozen indicators. Similar to the criterion of pan-Canadian coverage, the *Comprehensiveness* criterion assessed the inclusiveness of health services providers that submit data toward the indicator. For example, the mental illness hospitalization indicator includes data on mental health patients treated in general hospitals only, while hospitalizations at free-standing psychiatric institutions are not included due to the differences in data collection.

For the *Usage* criterion, we polled CIHI HSP staff responsible for interacting with clients on indicators and data requests. This provided a proxy for the level and extent of the indicator's usage by clients. The 56 indicators under evaluation were rated as High (n=33), Medium (n=15) or Low usage (n=8).

With regard to *Dimensionality*, breakdowns of indicator results by dimensions of sex and socio-economic status (SES) are available where applicable. Thus, 15 indicators are reportable by SES and 14 are reportable by sex.

In terms of *Timeliness, Reporting frequency and Accessibility,* all 56 indicators were publicly reported annually within 10
 months of the relavent data being available for analysis. At the time of the evaluation, all HSP indicators were accessible
 publicly through online publications such as the Health Indicators e-Publication. Additionally, a majority of facility-level
 indicators are available to providers through private online tools to allow for more granular breakdowns of results and peer
 comparative reports.

For the *Trendability* criterion, it was found that time trends vary by indicator. For example, the set of facility-level indicators was largely first reported beginning with 2007 data. Results for select regional indicators dated back to 1997. Overall, regional indicators possessed almost twice as many available years of results compared with facility indicators, a nature of the timing of reporting programs.

#### 45 <u>Importance</u>

As a proxy measure for *Relevance*, an environmental scan was conducted to understand stakeholder utilization of
 indicators. A total of 232 instances online were recorded. The top five indicators were Hospital Standardized Mortality Ratio
 (HSMR) (n=23), 30-Day Overall Readmission (n=18), Wait Times for Hip Fracture Repair (n=17), Ambulatory Care Sensitive
 Conditions (n=14), and Caesarean Section Rate (n=13).

52 Detailed statements on the *Actionability* of each indicator were provided to evaluation participants. Specifically, 53 summations on the purpose of indicator, strengths, caveats, and scientific evidence in support were considered. 54

To measure the degree of *Stakeholder follow-up*, we reviewed all instances of patient-level data requests from providers. In 2013-14, there were 298 requests, with 11 facility-level readmission indicators accounting for 58% of all requests (n=173).

#### EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS

1 The criterion Sufficient volumes quantifies the proportion of indicator results that are suppressed per CIHI's data privacy 2 protocols. In general, indicator results with cell counts less than five are suppressed, and results based on less than 50 3 denominator cases per hospital are flagged as low volume and unstable rates. Facility-level indicators are particularly 4 5 affected by low volumes and suppressed results: 23 of 27 facility-level indicators had at least one-fifth of all results flagged 6 as low volume. A further 7 of these indicators had at least one-fifth of all results suppressed due to small cell counts. At the 7 extreme, we note the 28-Day Readmission After Stroke and Acute Myocardial Infarction (AMI) indicators with ~75% low 8 volume rates and one-third of all results suppressed. 9

10 We performed Significance of variation analysis to determine the variability within indicator results. For example, the Hip 11 Fracture Surgical Procedures Performed Within 48 Hours indicators (both Within One and Across facilities) had the lowest 12 relative standard deviation values of 16% and 17%, respectively, indicating minimal differences across indicator results. 13 14

#### 15 Scientific Soundness

16 The criterion Data quality garnered the greatest discussion during Delphi reviews. Limitations of using administrative data 17 were considered. Examples of concern include the inability to assess indications for angiography for AMI patients for the 18 indicator Use of Coronary Angiography Following AMI, and the ability to properly identify denominator cases for the 19 Hysterectomy indicator. 20

22 The evaluation revealed that Validity reviews were performed for each indicator on an annual basis. These included 23 significance testing of risk factors, monitoring of diagnosis and procedure coding updates, and outlier and significant change 24 analyses. Indicators recommended for further consultation and R&D were identified as such mainly for the purpose of 25 seeking feedback from stakeholders on the validity and clinical relevance of current calculation methodologies. 26

27

21

The criterion Participation bias assessed whether data submission and participation in the calculation of indicator results 28 29 were a nature of voluntary participation. All but two indicators — Physician Specialists and General/Family Physicians per 30 100,000 Population — required mandatory participation. In other instances, such as indicators produced for long-term care 31 facilities, participation is not yet mandatory across the country, and therefore results published may contain a participation 32 bias. 33

34 **Feasibility** 35

Production cost was considered based on the extent of staff resources required to produce each indicator. Indicators with 36 37 complex linkages across multiple databases and those requiring building of episodes of care necessitate a larger degree of 38 resources.

39 40

#### Modified-Delphi sessions of CIHI technical and leadership groups

41 Mean Likert scores, recommendations and rationale are noted in tables 2, 3 and 4. Nine indicators were recommended as 42 candidates for retirement (Table 3), seven were identified as requiring additional consultation and three were 43 44 recommended to undergo further redevelopment (Table 2). Thirty-five indicators were recommended for retention (Table 45 4). The rationale to retain these HSP indicators was based on the assessment of all 18 evaluation criteria as a whole. 46 Although retained indicators correlate strongly with high mean Likert scores, this was only one contributor to the 47 recommendation. Ultimately, the discussion during the in-person Delphi sessions allowed for the most pertinent and 48 informative of the 18 evaluation criteria to be considered above others.

49 50

CIHI leadership and technical groups identified indicators for additional consultation and redevelopment. These indicator 51 52 recommendations were not forwarded to Consensus Conference participants, but were instead identified for internal R&D 53 efforts in the interim. 54

#### 55 Pre-Consensus Conference survey 56

Forty-eight Consensus Conference participants completed the online survey (response rate of 79%). Eighty-five percent of 57

conference participants had more than 10 years of health care experience. Geographic distribution of respondents 58 59 correlated well with Canada's population across provinces/territories. Stakeholders from federal and provincial government

#### **EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS**

agencies accounted for three-quarters of survey respondents, followed by regional health authority executives, hospital administrators and academic/research funding organizations. The mean survey agreement score (as a percentage of responses) for all nine indicators proposed for retirement was 70%, and was used as a benchmark for automatic ratification. The option to select No Opinion for each indicator under survey accounted for an average of 20% of responses (ranging between 12% and 30% across indicators); such an option was made available in the event that respondents held insufficient knowledge on the indicator or did not utilize the indicator within their setting; a response of Agreed, Disagreed or No Opinion was mandatory in the survey. 

#### 11 National Consensus Conference

Of the nine indicators recommended for retirement, six received more than 70% agreement as a proportion of responses in the pre-conference survey, and therefore were automatically accepted for retirement (Table 3). The remaining three indicators were discussed as a group, and subsequently also ratified for retirement by conference participants. The majority of indicators recommended for retirement were condition-specific readmission indicators. Ultimately, the decision to retire these indicators was based on appropriateness for continued public reporting. While these indicators were ratified for retirement over concerns of rate stability and small numbers, facilities can continue to calculate and monitor these indicators through CIHI private reporting tools. Consensus on retiring these indicators was achieved with greater ease given that a provider's capacity to continue to privately monitor performance would be maintained. 

Two contextual health human resources indicators at the regional level — Physician Specialists and General/Family Physicians per 100,000 Population — were also included in the modified Delphi review process, and rated low in Likert Scale scoring (both received a mean score of 3.2). While these indicators provide some context on HSP characteristics, they are already reported elsewhere within CIHI. It was agreed to continue reporting on these indicators but outside of the HSP framework.

Table 4 lists 35 HSP indicators retained for continued public reporting. Although retained indicators correlate strongly with high mean Likert scores, this was only one contributor to the recommendation. For example, the regional level Caesarean Section Rate indicator received a mean Likert score of 4.8 from the technical group, but was retained for public reporting after discussion by the leadership group due to continued concerns over high rates in Canada and therefore a need for continued monitoring.

#### EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS

#### Discussion

2 This exercise proved to be an informative, objective, systematic, transparent, inclusive, and likely repeatable process for 3 evaluating and reconfirming a national set of HSP indicators. Overall, the approach of using 18 sub-criteria was manageable 4 and informative, with feedback from participants that the added information and context made it easier to make a final 5 6 disposition recommendation for each indicator. The overall timeline of the evaluation process from inception to completion 7 was 18 months. Three distinct phases stand out, each requiring approximately six months to complete: initial R&D of the 8 evaluation plan, executing the evaluation internally at CIHI, and achieving consensus across stakeholders.

9 10

1

An initial Likert score of indicators provides a baseline to proceed with group Delphi reviews. We found it beneficial to begin 11 with the lowest scores and work our way to the highest rated indicators. We also found it operational to have our technical 12 group first review indicators and to pass on recommendations to a leadership group that would consider these in addition 13 14 to their knowledge and understanding of the use of HSP information in the field. The iterative process of having participants 15 first review indicators independent of other Delphi members and to then convene as a group to discuss findings allowed for 16 a balanced and participatory discussion among participants. These iterative methods ensured a summative process 17 whereby findings were transparent and confirmed at each stage. 18

19

The national Consensus Conference provided an opportunity to pilot-test the results of a rigorous, mostly internal 20 21 methodology for evaluating indicators produced by CIHI. Most recently, CIHI has been incorporating the learnings from this 22 exercise into a broader "lifecycle" approach to indicator development, evaluation and retirement recognizing that all too 23 often there is a tendency to add new indicators to the suite of those reported paying little attention to the utility of those 24 reported in some instances for years. The internally developed evaluation process including the 18 criteria used for 25 assessing previously reported indicators will also lend itself to mid-cycle reviews of suites of indicators that could be 26 modified for such a process. The ability to affirm our internal process with external stakeholders at a national conference 27 provided further confidence in the process. And, while stakeholders appreciated the opportunity to review and ratify our 28 29 findings, going forward, they expressed comfort with CIHI implementing a systematic evaluation of the indicators and 30 making decisions about reporting. There was congruence in opinion on the suitability of HSP indicators for public reporting 31 throughout the evaluation process, beginning with Likert scores and assessments from CIHI technical staff, to CIHI 32 leadership, and lastly with stakeholders. 33

34

44

#### Strengths and weaknesses of the study 35

We recognize that the overall evaluation process required considerable time and resources, there are important benefits to 36 37 such a comprehensive approach. For example, we ensured a transparent and sequential evaluation, whereby discourse and 38 findings were accumulated and presented in a summarized manner at each phase. We solicited feedback from a wide array 39 of expertise including those responsible for monitoring the results of these indicators on a regular basis. An external 40 moderator facilitating the discussion ensured independence during the consensus process. These processes have been 41 described as favourable conceptual approaches to aid exercises of indicator development, maintenance, and evaluation 42 [14]. 43

45 One main weakness of this process was the lack of involvement of the "patient/public" voice in evaluating the utility of 46 CIHI's current suite of publicly reported health system performance indicators. Traditionally the approach to health system 47 performance reporting has largely been targeted to system decision makers. With the growing recognition that health 48 system performance includes measuring things that are important and relevant to the patient/public, it is clear that the 49 patient/public perspective needs to be embedded in future aspects of this work. In 2013, CIHI solicited input from 3,000 50 Canadians (randomized, representative sample) through small group dialogues and online questionnaires about which types 51 52 of indicators and domains of health system performance they would like to see publicly-reported. In an attempt to obtain 53 broader input to the evaluation process discussed in this paper, the same survey sent to Consensus Conference participants 54 was made available on CIHI's website for public participation. The survey responses from the general public were 55 highlighted and considered at the Consensus Conference. However, a more systematic approach to including the 56 patient/public perspective within the "lifecycle" approach to development, evaluation and retirement is needed going 57 forward. 58

#### **EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS**

1 Shekelle [16] notes there is little agreement on methodologies for developing performance indicators, and this can also be 2 said regarding their evaluation. Nonetheless, Stelfox and Straus [14] emphasize the importance of clearly establishing the 3 chosen evaluation criteria in advance of launching a consensus process. In the majority of the studies we reviewed and cite, 4 5 6 a smaller number of evaluation criteria were applied: most often, usability, importance, scientific soundness, and feasibility (or a variation thereof that drew upon similar domains). Conversely, we found it helpful to apply multiple sub-criteria to 7 comprehensively reflect the evaluation of indicators for their suitability of ongoing public reporting. Furthermore, providing 8 a more granular evaluation schema for participants ensured more consistent definitions of domains and structured 9 evidence/results for evaluators' consideration. Nonetheless, while these evaluation criteria were informative and applicable 10 to this precise context, not all would apply for other evaluation purposes. Further efforts are necessary to determine the 11 level of customization required to ensure that the process and criteria are applicable to other sectors of care and types of 12 13 indicators. 14

15 In addition to convening an in-person consensus conference (or expert panel) to evaluate indicators, Santana et al [17] 16 forwarded their evaluation survey to 101 trauma centres across four countries involved in the use and assessment of injury-17 care indicators. Moreover, a novel subsequent processes has been described by Bobrovitz et al [18] whereby the discussion 18 occurring throughout the consensus conference is transcribed and undergoes qualitative content analysis to identify key 19 themes raised throughout the deliberations. These additional activities can provide complementary evidence to the 20 21 evaluation process, such as qualitative findings to an otherwise objective and quantitative exercise, and reaching a broader 22 group of stakeholders and users of health measures. 23

24 There are certain characteristics of the Canadian health care system that are favourable for such an evaluation exercise. As 25 the national healthcare system information steward, CIHI receives data for virtually all hospitalizations across the country in 26 a standardized manner. All but two of the 56 HSP indicators are calculated using this standardized data source. Therefore, 27 the application of 18 evaluation criteria to these indicators can be done so in a systematic process so that objectivity is 28 29 maintained. A centralized healthcare information system is more conducive for cross-country analysis and reporting [19]. 30 This also extends to the convening strength of CIHI to bring together stakeholders from all provinces and territories to agree 31 on a national agenda. 32

To balance the limiting aspects of a Delphi exercise on a set of existing indicators, the Consensus Conference also included
 working group sessions on identifying priority areas for future indicator development (organized by health system
 quadrants of Inputs and Characteristics, Outputs, Outcomes and Social Determinants of Health). From these discussions,
 along with a cross-country consultation process, CIHI has embarked on a path to develop new indicators for the domains of
 safety (e.g. infections), mental health and addictions (alcohol attributable hospitalizations), and others relating to recently
 identified priority populations such as seniors and aging (e.g. palliative care), and children and youth.

#### 41 42 <u>Conclusion</u>

The proliferation of health measures required to fulfill reporting gaps occurred with minimal consideration to alignment and utility with pre-existing indicators. Not surprisingly, then, stakeholders were overwhelmingly in favour of implementing a process that would result in a leaner, more applicable suite of HSP indicators.

CIHI will gradually expand this evaluation methodology to applicable sectors of care. We will also continue to work with
 external partners to reduce indicator chaos and increase alignment with reporting requirements across the country [6].

This exercise generated identified analytical alignment actions that can be taken at CIHI throughout indicator production
 and maintenance with a view to reduce indicator chaos. Furthermore, we gained new knowledge about how the HSP
 indicators we produce are used by stakeholders both through an internet-based environmental scan and via discussions
 held at the Consensus Conference [10].

In line with established practices of convening a Consensus Conference every five years, we feel that it is highly beneficial to
 inform those discussions with a wholesale and systematic criteria-based review of indicators just prior. A broad consultation
 process encompassing diverse public health stakeholders from across the country helps ensure the development and use of

#### **EVALUATION OF HEALTH SYSTEM PERFORMANCE INDICATORS**

- , identify . indicators most appropriately reflecting the health of populations and the performance of health systems [20]. Similarly, a retrospective exercise on national HSP practices can identify important lessons, of which the selection of indicators suitable
- for public reporting is an integral component [21].

Table 1 – Evaluation criteria	
Domain/Criterion	Definition
<u>Usability</u>	
• Granularity of reporting	Reporting at national, provincial/territorial, regional and facility levels
• Pan-Canadian coverage	Extent of participation from all provinces and territories
· Comprehensiveness	Proportion of providers submitting data for the indicator
• Usage	Level and extent of usage
Dimensionality	Ability to break down results by age, sex, socio-economic status, and other dimensions
· Timeliness	Latest year of available results
· Reporting frequency	Whether indicator is reported quarterly, annually or other
· Accessibility	Whether the indicator is publicly and/or privately reported
· Trendability	Number of years of available results for trending
Importance	
· Relevance	Environmental scan identified uses of indicator by stakeholders
· Actionability	Extent to which providers can meaningfully influence the indicator
Stakeholder follow-up	Number of data and methodological requests within last fiscal year
· Sufficient volumes	Percentage of results suppressed (due to low counts)
· Significance of variation	Degree of variation across reported values
<u>Scientific Soundness</u>	
• Data quality	Strength of data quality, ability to validate results, based on standard
· Validity review	Extent and frequency of reviewing indicator's validity/methodology
· Participation bias	Mandatory or voluntary participation by providers
<u>Feasibility</u>	
Production cost	Extent of staff/resources to produce indicator

	Knee Replacement	0.4	reporting tools.	7378	
	90-Day Readmission After	6.4		72%*	
	Hip Replacement	0.4		7270	
	28-Day Readmission After	6.2		58%	
	Stroke				
	Use of Coronary Angiography Following AMI	6.4	Angiography may not be indicated for every AMI patient, depending on his or her clinical history, and the clinical appropriateness of angiography is difficult to ascertain from the administrative hospitalization data. Therefore, it is challenging to interpret and compare the results for this indicator.	78%*	
Facility	Hip Fracture Surgical Procedures Performed Within One Facility (48 Hours)	6.4	This indicator does not measure the true proportion of surgeries performed within 48 hours of admission to an acute care hospital, since it does not account for transfers across hospitals. Many patients are transferred from their initial admitting acute care facility to another facility for surgery. The indicator Hip Fracture Surgical Procedures Performed Within 48 Hours, which measures total time across all acute care facilities, will continue to be produced and reported on.	72%*	
	28-Day Readmission After AMI	6.4	Concerns have been raised regarding hospitals' ability to take action on this indicator. It is felt that with the regionalization of cardiac care, it is more appropriate to measure readmission after AMI at the regional level (by patient residence) than at the hospital level. In addition, having a low volume of cases leads to unstable rates and to the suppression of a large number of results for public reporting. Therefore, it was proposed to keep the Readmission After AMI indicator at the regional level and to retire the facility-level indicator. Furthermore, readmissions after AMI are included in the 30-Day Overall Readmission indicator at the facility level.	59%	
	Primary Caesarean Section Rate	4.6	A new indicator (Low-Risk Caesarean Section) measures the rate of deliveries via Caesarean section among singleton term cephalic pregnancies for women without placenta previa or previous C-section. Since this new indicator is limited to women who have not had a previous C-section, it can take the place of Primary Caesarean Section Rate and be a better indicator of appropriateness.	57%
