Abstract

Objectives: To describe the psychometric testing including Rasch analysis of the Claim Evaluation Tools in English speaking populations in Uganda and Norway.

Setting: We developed the Claim Evaluation Tools to evaluate members of the public's ability to assess treatment claims to be used in two randomised trials. The Claim Evaluation Tools consists of a battery of objective and flexible multiple-choice items.

Participants: We administrated four subsets of multiple-choice items to 1114 people, of which 685 were children and 429 were adults (including 171 health professionals). We scored all items dichotomously. Individual item fit statistics were estimated using pairwise maximum likelihood estimation available in the RUMM2030 analysis package and marginal maximum likelihood estimation available in the ConQuest4 analysis package. Possible dimension violations and response violations of local independence were studied using the PCA/t-test procedure and by inspecting the residual correlation matrix. We analysed differential item functioning for available person factors using the RUMM2030.

Results: The four subsets had satisfactory reliability, and most items did not over or under discriminate or function differently across subgroups of participants. There was no important response dependence, and one unidimensional latent trait was identified. The items had high difficulty. The spread (standard deviation) in the variable «ability» was as expected.

Conclusion: These results suggest that the items are reliable in the settings in which they have been tested. Items with sub-optimal fit will be considered deleted or repaired. We encourage further testing of the Claim Evaluation Tools in other contexts. All items will be available on request for non-commercial use through the website Testing Treatments interactive (www.testingtreatments.org).

Strengths and limitations of this study

- To our knowledge, this is the first psychometric testing including Rasch analysis of a set of evaluation tools that objectively measure people's ability to apply Key Concepts people need to know to assess claims about treatment effects
- We have used robust methods in two settings to test the reliability of the items, allowing for evidence informed revisions of any items with sub-optimal fit
- Our analysis suggest that the items are reliable in these settings and can be used for evaluating the effects of interventions to promote understanding of the Key Concepts
- This study provides evidence of the reliability of the items in two contexts, and the fit with the Rasch model when used in other settings is unknown.
- The items tested in this study was tested in English in English speaking populations, the reliability of the items in other languages remains to be tested.

Background

People are confronted with claims about treatment effects daily. This includes claims about the effects of changes in health behaviour, screening, other preventive interventions, therapeutic interventions, rehabilitation, and public health and health system interventions that are targeted at groups of people (1-4). Many of these claims are not based on evidence from fair comparisons of treatments, and many patients and health professionals alike don't have the necessary tools to assess the reliability of these claims (5-11). Being able to think critically and make informed decisions is essential for engaging patients in clinical decisions and citizens in policy decisions, and affects people's health and use of resources (10, 12-15).

The aim of the Informed Healthcare Choices (IHC) project is to develop and evaluate learning resources to help people to assess treatment claims and make informed healthcare choices. The project has developed primary school resources and a podcast series to improve the ability of children and their parents to assess claims about treatment effects. We have piloted these resources in Uganda, Kenya, Rwanda and Norway, and the effects of the resources will be tested in randomized trials in Uganda (16, 17).

Until recently, there has not been a list of the Key Concepts that people must be able to understand and apply in order to assess claims about the effects of treatments. The development of such a list was the starting point for developing the IHC resources and the Claim Evaluation Tools, which will be used to evaluate the effects of the resources (18). Although a large number of studies have been conducted in different areas to improve critical thinking skills related to one or more of these Key Concepts, this research is heterogeneous and outcomes are measured inconsistently (19). Furthermore, available

1
2
3 instruments used to map or evaluate people's understanding of claims about treatment effects include
4
5 only a handful of the Key Concepts (19). Given this diverse, international interest, a set of tools is
6
7 needed both to evaluate the effects of interventions to promote understanding of the Key Concepts and
8
9 to assess the extent to which people are able to assess claims about treatments and make informed
10
11 healthcare choices.
12
13

14
15
16
17 The Claim Evaluation Tools consist of a battery of open-access, objective multiple-choice items
18
19 addressing each of the Key Concepts. Researchers, teachers and others can select those that are
20
21 relevant for specific populations or purposes. The items includes scenarios intended to be relevant
22
23 across different contexts. They can be used for children (from ages 10 and up) and adults, including both
24
25 patients and health professionals (20). In another paper we have described the iterative development of
26
27 the Claim Evaluation Tools, including qualitative and quantitative feedback from experts and end-users
28
29 in Uganda, Kenya, Rwanda, Norway, United Kingdom and Australia (20). Based on suggested revisions by
30
31 experts and end-users, we tailored the item content and formats with the intention of improving the
32
33 reliability and validity of assessments. The items were found to have face validity by people with
34
35 expertise in methodology, and end-users judged the items to be relevant and acceptable in their
36
37 settings (see figure 1 for example of format). The Claim Evaluation Tools were developed in English, but
38
39 is currently being translated into Lugandan (Uganda), Norwegian, German, Spanish (Mexico), and
40
41 Chinese. This paper describes the psychometric testing including Rasch analysis of a sub-set of the Claim
42
43 Evaluation Tools administered in English in English speaking populations in Uganda and Norway.

1
2
3 Rasch analysis relies on item response theory and is based on the requirement that the comparison of
4 two people are independent of which items are used within the set of items assessing the same variable
5
6 (21-24). Furthermore, in the Rasch model the total score across items completely describes a person's
7
8 standing on a variable. Rasch analysis has been used successfully in many disciplines including health
9
10 research, and can be applied to both dichotomous and polytomous data (21, 25, 26). Rasch analysis is
11
12 used to check the degree to which this scoring and summing-up across items is defensible in the data
13
14 collected (21, 23, 25). For example, if you want to compare the ability to assess claims in two groups,
15
16 such as patients and health professionals, it is important to be sure that the items work in the same way
17
18 in the two groups. Rasch analysis also provides an excellent basis for revising individual items. When
19
20 checking the items' fit to the Rasch model, misfit to the model can be easily diagnosed and items can be
21
22 revised to improve fit (27). In this way, the Rasch analysis represents a dynamic approach to achieving
23
24 construct validity, in which revisions are informed by the evidence (27).

44 **Methods**

45 **Rasch analysis and item response theory**

46
47 Item response theory focuses on individual item responses and observed "trait" score estimates (28). A
48
49 trait refers to a person attribute. In this paper, a person trait score estimate or person location estimate
50
51 β refers to the attribute "ability to critically assess claims about treatment effects" and an item difficulty
52
53 or item location estimate δ refers to an item's difficulty.
54
55
56
57
58
59
60

1
2
3 The item response theory model referred to as the simple logistic Rasch model for dichotomous
4 responses is represented mathematically as $P(x=1)=\exp(\beta-\delta)/(1+\exp(\beta-\delta))$. It models the probability P of
5 a correct answer ($x=1$) as the difference between the item difficulty and the person ability $\beta-\delta$ expressed
6 in logits. The unit “logit” or “log-odds unit” refers to $\ln[(\text{probability of success})/(\text{probability of}$
7 failure)]= $\beta-\delta$ (24). When the item difficulty matches the person ability, $\beta=\delta$ and the probability of a
8 correct answer is 0.5 or 50%. When $\beta>\delta$ or $\beta<\delta$ the probability of answering correctly is above or below
9 50%, respectively.

10
11
12
13
14
15
16
17
18
19
20 When data conform to the Rasch model, ability is measured consistently across the trait level scale with
21 low measurement error. Hence, reliability follows from the Rasch model. In item response theory,
22 measurement error is calculated as the standard error of estimate (SE of estimate= $1/\sqrt{I}$) being the
23 inverse of the square root of the test information (I). SE of estimate varies across the trait level
24 scale as we tend to be better at measuring persons where there is more information i.e., more items
25 telling us the strengths (correct answers) and weaknesses (wrong answers) of a person. As most items'
26 difficulty is located close to the middle of the person ability distribution we tend to measure less well at
27 the extremes where there are fewer items and accordingly less information. The precision of
28 measurement is quantified by standard errors in item response theory. Another benefit of item
29 response theory measurement is that the scale of measurement is an interval logit scale.

30
31
32
33
34
35
36
37
38
39
40
41
42
43
44 As mentioned above, Rasch analysis is a very useful tool for diagnosing problems with the items.

45
46 Revisions can then be made to improve fit, either by revising or deleting response-options with sub-
47 optimal fit, or by deleting whole items, informed by the evidence (27). This can be done by visual
48 inspection of fit to the Item Characteristic Curve, Bonferroni adjusted high chi-square probability, and
49 exploring the mean z-score by response alternative. The Item Characteristic Curve indicates the Rasch
50
51

2
3 model's theoretically expected probability of answering correctly as a function of ability on the latent
4
5 trait scale (see Figure 2 for an example of an Item Characteristic Curve).
6
7

8
9 *Please enter figure 2. The Item Characteristic Curve*

10
11 The mean ability estimates of the four class intervals used to group the persons based on ability are
12
13 marked on the scale (in logits) (in this example taken from one of the Claim Evaluation Tools' item sets: -
14
15 1.83, -1.18, -0.70 and 0.50). The imposed observed values indicate the proportion of correct answer in
16
17 each interval. The inflection point (0.52, 0.50) refers to the item difficulty estimate (0.52) and the
18
19 probability of a correct answer (0.50) for the matching person ability. The dashed line is the upper
20
21 asymptote for probability. See Tables 1 and 2 for examples of difficulty and fit statistics and item mean
22
23 z-scores.
24
25
26
27

28
29 *Please enter Table 1. Difficulty and fit statistics for the item*

30
31
32 *Please enter Table 2. Mean z-scores for the group choosing each response alternative*
33
34

35 When the data conform to the Rasch model, the person's ability (what we measure) and the items (our
36
37 measurement device) are independent. This is a necessary requirement of objective measurement
38
39 referred to as *specific objectivity* (29). This item-invariant measurement of persons and person-invariant
40
41 calibrations of items indicate *sample independence*. When the data conform to the Rasch model, the
42
43 raw score sum of responses to the items (a measurement at the ordinal level) is a *sufficient statistic*; i.e.,
44
45 it contains all the information needed to estimate the person location. The Rasch model transforms
46
47 ordinal data into an interval logit scale implying *additivity* on the scale (30-32). The requirement of
48
49 invariance follows from the Rasch model (22). If an item difficulty measure is different for two levels of a
50
51 person factor - that is, for two groups of respondents (for example children and adults) - that item
52
53 exhibits "within item bias" referred to as DIF and invariance is violated (33).
54
55
56
57

1
2
3 The local independence assumption presupposes unidimensional data and no response dependence
4
5 between pairs of items (24, 34). The requirement of unidimensionality is met when one latent trait
6
7 sufficiently explains the variance shared among the item responses. It follows from this that one variable
8
9 “explains” all the correlations between the items. If responding to the items requires abilities from two
10
11 or more dimensions, two or more latent traits are needed to account for the correlations between the
12
13 items. This indicates bi-dimensional or multidimensional data (i.e., a composite of several
14
15 unidimensional subscales), and we would fit a multidimensional Rasch model using the framework of
16
17 the Multidimensional Random Coefficients Multinomial Logit model to account for the correlations
18
19 between the unidimensional subscales (35). The prescriptive Rasch model is confirmatory and could, in
20
21 cases where the researchers are concerned about the dimensionality of their scale, be accompanied by
22
23 confirmatory factor analysis (CFA). If an item offers clues to solve a subsequent item or pairs of items
24
25 share specific similarities beyond what the latent trait(s) can account for, we refer to this as response
26
27 dependence. The result is redundancy in the data and inefficient measures. Multidimensionality and
28
29 response dependence violates the requirement of local independence.
30
31
32
33
34
35
36
37
38
39

40 **Participants, setting and test administration**

41
42 We included two samples in the psychometric testing of the items, a Ugandan sample including primary
43
44 school children (approximately age >10) and adults, and a Norwegian sample including primary school
45
46 children (approximately age >12). In both settings, the samples included people who had received some
47
48 training in the Key Concepts through the pilots of the IHC learning resources. The Ugandan sample
49
50 included health professionals. We recruited children, parents and other adults through our own
51
52
53
54
55
56
57
58
59
60

1
2
3 networks and through networks of teachers and journalists that were established at the start of the IHC
4
5 project (36, 37)
6
7

8
9 For this evaluation, we used classical psychometric testing for reliability (Cronbach's Alpha), for which a
10
11 value of 0.7 or higher is considered adequate), and Rasch analysis. There is no consensus on the sample
12
13 size needed to perform a Rasch analysis (38). This is a pragmatic judgement that takes account of the
14
15 number of items being evaluated and the statistical power needed to identify DIF. We aimed to achieve
16
17 approximately 250 respondents for each of four item sets. We also chose to include a group of children
18
19 who had participated in a pilot of the IHC primary school resources at an international school in Norway.
20
21 Although this was a small sample, it would give us some indication of the fit to the Rasch model in an
22
23 international population, and provide information on difficulty and differential item functioning in the
24
25 two different settings. In both settings, we administered the Claim Evaluation Tools in English, since this
26
27 was the official school language in both the Norwegian International School as well as the Ugandan
28
29 Schools.
30
31
32

33
34 We administrated all items addressing 22 of the 32 concepts (see Figure 1 for example of format). We
35
36 judged ten of the 32 Key Concepts too difficult for people in our target groups in Uganda, and
37
38 consequently items addressing these Key Concepts were not addressed in the IHC resources that were
39
40 pilot tested (36, 37). Because of the large number of items to be tested, we distributed the items across
41
42 four sets (of which the small Norwegian sample only responded to one set of items). Demographic
43
44 variables included age (child/ adult), educational background (health professional or not health
45
46 professional) and exposure to the concepts through IHC interventions (yes/ no). In the development of
47
48 the Claim Evaluation Tools, low literacy skills were identified as a potential barrier in the Ugandan
49
50 setting (20). Consequently, literacy was a variable that could introduce DIF in the Claim Evaluation Tool
51
52 items data. To explore this, a four-item English reading test was included to explore text recognition and
53
54
55
56
57
58
59
60

1
2
3 understanding as an indication of the respondents' literacy level (see Appendix 1). The items were
4 designed to resemble the multiple-choice items addressing the Key Concepts. The first two items
5
6 required the respondents to identify the correct text sequence in the scenario. The latter two items
7
8 assessed whether the respondent was able to integrate the information in the scenario.
9
10
11

12 13 14 15 16 **The components of the Rasch analysis**

17
18 We scored all items dichotomously. Individual item fit statistics, such as Bonferroni adjusted chi-square
19
20 probability, infit and t-value, were estimated using pairwise maximum likelihood estimation available in
21
22 RUMM2030 and marginal maximum likelihood estimation available in ConQuest4 (39-45). Possible
23
24 dimension violations and response violations of local independence were studied using the PCA/t-test
25
26 procedure and by inspecting the residual correlation matrix estimated in RUMM2030 (46).
27
28

29
30 Dimensionality and response dependence might similarly be assessed using the unidimTest function in
31
32 the ltm R-package and the Q3 statistic in the sirt R-package, respectively (47, 48). Our analysis of DIF for
33
34 available person factors was carried out using RUMM2030.
35
36
37
38
39
40
41

42 **Results**

43
44
45 The total sample included 1114 people, among whom 685 were children and 429 were adults (including
46
47 171 health professionals). Of these 1114 people, 329 had received some form of training related to the
48
49 Key Concepts. The Norwegian sample equalled 5% (59 respondents) out of the total respondents. The
50
51 respondents completed most of the items, and the mean number of missing or incorrectly filled in
52
53
54
55
56
57
58
59
60

1
2
3 responses was <1%. Less than 1/3 responded correctly to all four reading test questions in the Ugandan
4
5 sample, indicating a low-literacy level in English in this particular sample.
6
7
8
9

10 11 12 **Item discrimination and fit**

13
14
15 Most of the items conformed well to the Rasch model and only a few items showed evidence of DIF. In
16
17 set 1 (the only set applied in both Uganda and Norway), six items had DIF based on setting (Norway and
18
19 Uganda). A few items in each of the four sets also had some DIF for age and group (see Table 3).
20
21

22
23 *Please enter Table 3. Reliability, response dependency and DIF by item set*
24
25
26
27

28 **Targeting and reliability**

29
30
31 Cronbach's Alpha was satisfactory with the exception of set 4, which was below the desired threshold
32
33 (see Table 3). Overall, the items developed to assess claims about treatment effects had high difficulty in
34
35 the target population, with no very easy items. However, there were no extremely difficult items. The
36
37 observed logits for sets 1, 2, 3 and 4 were -0.81, -1.06, -1.15 and -1.15 respectively. The spread
38
39 (standard deviation) in the variable «ability» was as expected.
40
41
42
43
44
45
46

47 **Possible dimension and response violation of local independence**

48
49
50 Results indicated that all four sets measured a sufficiently unidimensional latent trait. There were no
51
52 specific sub-dimensions measuring different traits. Hence, one major dimension governs the responses
53
54 to the items (use of principal component analysis of residuals/ dependent t-test procedure).
55
56
57

1
2
3 Only weak dependence was found in two items for set 1 with a residual correlation of 0.21. We did not
4
5 observe any response dependence in the other three sets.
6
7

8 9 **Discussion**

10
11 We have developed the Claim Evaluation Tools using qualitative and quantitative feedback from
12
13 methodologists and end-users in six countries. This study reports the findings of the first psychometric
14
15 testing conducted in two settings, Uganda and Norway, of items addressing 22 out of 32 Key Concepts.
16
17 Overall, we found that these subsets of the Claim Evaluation Tools had high reliability. Most of the items
18
19 did not over-or underdiscriminate, or function differently across subgroups of participants. No
20
21 important response dependence was identified, and all four sets measured a sufficiently unidimensional
22
23 latent trait. The findings of this study will inform decisions about revising or deleting items with sub-
24
25 optimal fit to the Rasch model.
26
27

28
29 Feedback on the items from experts and end-users suggested that the items were difficult (20). Our
30
31 Rasch analysis confirmed this. Moreover, the respondents reading skills was found to be low in the
32
33 target population in Uganda. This suggests that efforts should be made to simplify the text in the
34
35 scenarios and editing the response options to improve readability. Removing response options in items
36
37 with sub-optimal fit to the Rasch model could also contribute in making the items less difficult.
38
39

40
41 A limitation of this study is that we tested the items in only two settings, Uganda and Norway, and the
42
43 fit with the Rasch model when used in other settings is unknown. Although we found few items with
44
45 cross-cultural differential item functioning, any other application of the Claim Evaluation Tools in other
46
47 countries should be tested using Rasch analysis. Furthermore, we did not include gender in the analysis,
48
49 which could introduce DIF, and this will be explored in further testing.
50
51
52
53
54
55
56
57

1
2
3 There has been encouraging interest in using the Claim Evaluation Tools in settings other than the
4 countries included in the IHC project, and researchers in Norway, Mexico, Germany and China are
5 currently translating and testing the multiple-choice items in their settings. In addition, the items
6 addressing the Key Concepts judged to be more advanced and which were not tested as part of this
7 study are currently being tested online through testingtreatments.org including people with expertise in
8 evidence based medicine. We are also developing items to assess intended behaviours, attitudes
9 towards assessing treatment claims and self-efficacy.

21 All Claim Evaluation Tools will be freely available for non-commercial use on request through the Testing
22 Treatments interactive website (www.testingtreatments.org). We will tag individual items by the
23 settings in which the items have been tested, including information about the people in which the item
24 was tested, and how it was tested (qualitative feedback or psychometric testing). We will also make the
25 item's properties based on any psychometric testing available, including information about reliability
26 and difficulty (22, 24). We will tag items that have been newly developed or revised as 'new' and
27 'awaiting assessment'. This will provide transparency and make the items easily accessible to those who
28 would like to use them in teaching or for research activities.

40
41

42 For the pilots and statistical tests performed as part of this development work, we scored the items as
43 percent correct per item and calculated the overall percent correct responses across items for
44 individuals. However, mean scores can be difficult to interpret. To supplement this, it is possible to use
45 an absolute (criterion referenced) standard to set a passing score i.e. a cut score; e.g. for passing or
46 failing. The judgement about the required level of achievement is pragmatic, and there are several ways
47 of doing this (49-51). For the items that will be used in the trial of the resources, we will establish criteria

10 **Conclusion**

11
12 Based on psychometric testing using Rasch analysis in Uganda and Norway, we found that the tested
13
14 instruments were reliable and most of the items conformed to the Rasch model. Taken together with
15
16 our previously reported findings, these results suggest that the Claim Evaluation Tools we have tested
17
18 are reliable and have face and construct validity in the settings in which they have been tested. Items
19
20 with sub-optimal fit will be considered deleted or repaired. We encourage further testing of the Claim
21
22 Evaluation Tools in other contexts.

30

31 **Authors' Contributions**

32
33 AA, ØG, AO wrote the protocol and the IHC group provided comments to this protocol. The Claim
34
35 Evaluation Tools were developed by the IHC group. AA coordinated all of the development and
36
37 evaluation process with support from AO. DS, AN and KO performed the data collection and data entry
38
39 from the field testing. ØG and AA prepared the data files for the analysis, and ØG conducted the Rasch
40
41 analysis. AA authored this manuscript with significant input from the IHC group.

50 **Acknowledgements**

1
2
3 We are deeply grateful to all of the enthusiastic children, parents and teachers that contributed to this
4
5 project. We would also like to thank the IHC advisory panel, and the other researchers and
6
7 methodologists that provided their advice in the development process.
8
9

10 11 12 **Funding and competing interests**

13
14 The IHC project is funded in part by the Research Council of Norway- GLOBVAC project 220603. The
15
16 authors declare no conflicts of interests.
17
18

19 20 21 **Ethical approval**

22
23 Ethical approval was sought by the IHC project representatives in each country.
24
25

26 27 28 **Data sharing statement**

29
30 All data are published as part of this study or can be found at datadryad.org. All Claim Evaluation Tools
31
32 are available upon request for non-commercial use.

1. A doctor did a study to find out if drinking tea keeps people from getting sick. The doctor tossed a coin to decide who should get the tea and who should not. People who got tea went to the doctor's office every day to drink their tea. At the end of the study, people who got the tea were less likely to be sick than those who got no tea.

Based on the text above, please answer the following questions:

1.1 Who went to the doctor's office every day?

Options:

- A) People who did not get tea
- B) People who got tea
- C) Everyone
- D) People who got sick

Answer:

1.2. How did the doctor decide who should get tea?

Options:

- A) By tossing a coin
- B) By asking people what they would like
- C) They gave tea to those who were more likely to be sick
- D) They asked people who came to their office

Answer:

1.3. What was the treatment?

Options:

- A) Tea
- B) Sleep
- C) The study
- D) The doctors

Answer:

1.4. What was the result of the study?

Options:

- A) Drinking tea can help people from getting sick
- B) Doctors should toss coins when doing studies
- C) People should go to the doctor if they are sick
- D) Not drinking tea can help people from getting sick

Answer:

BMJ Open

Measuring ability to assess claims about treatment effects: A latent trait analysis of items from the "Claim Evaluation Tools" database using Rasch modelling

Abstract

Background: The Claim Evaluation Tools database contains multiple-choice items for measuring people's ability to apply the key concepts they need to know to be able to assess treatment claims. We assessed items from the database using Rasch analysis to develop an outcome measure to be used in two randomised trials in Uganda. Rasch analysis is a form of psychometric testing relying on Item Response Theory. It is a dynamic way of developing outcome measures that are valid and reliable.

Objectives: To assess the validity, reliability, and responsiveness of 88 items addressing 22 key concepts using Rasch analysis.

Participants: We administered four sets of multiple-choice items in English to 1114 people in Uganda and Norway, of which 685 were children and 429 were adults (including 171 health professionals). We scored all items dichotomously. We explored summary and individual fit statistics using the RUMM2030 analysis package. We used SPSS to perform distractor analysis.

Results: Most items conformed well to the Rasch model but some items showed evidence of differential item functioning or needed revision. Overall, the four item sets had satisfactory reliability. We did not identify significant response dependence between any pairs of items and, overall, the magnitude of multidimensionality in the data was acceptable. The items had a high level of difficulty.

Conclusion: We found that most items that we tested had satisfactory fit to the Rasch model. Following revision of some items, informed by the findings from this study, we concluded that most of the items were suitable for use in an outcome measure for evaluating the ability of children or adults to assess treatment claims.

Strengths and limitations of this study

- To our knowledge, this is the first Rasch analysis of multiple-choice items that measure people's ability to assess claims about treatment effects.
- We have used robust methods to evaluate the items' validity and reliability in two settings, allowing for evidence informed revisions.
- Our analysis suggests that most items have acceptable model fit and can be used in the settings where they were tested.
- The items might function differently when translated or used in other settings.

For peer review only

Background

People are confronted with claims about treatment effects daily. This includes claims about the effects of changes in health behaviour, screening, other preventive interventions, therapeutic interventions, rehabilitation, and public health and health system interventions that are targeted at groups of people. A “treatment claim” is something someone says about whether a treatment causes something to happen or to change; for example, that Vitamin C prevents you from getting the common cold. A claim can be true or can be false (1-4). Many of these claims are not based on evidence from fair comparisons of treatments, and many patients and health professionals alike do not have the necessary skills to assess the reliability of these claims (5-11). Being able to think critically and make informed decisions is essential for engaging patients in clinical decisions and citizens in policy decisions (10, 12-14).

Interest in promoting critical thinking cuts across disciplines (15). There are many definitions and conceptualisations of critical thinking. In the learning sciences, critical thinking is defined as “purposeful, self-regulatory judgment that results in interpretation, analysis, evaluation, and inference, as well as explanations of the considerations on which that judgment is based” (16). There is debate about the extent to which critical thinking skills are “generic” and the extent to which they are content specific. Critical thinking is also a component of health literacy (17). In health literacy studies, critical thinking is content specific, focussing on people’s ability to think critically about health information. However, definitions of this component of health literacy are often fuzzy. They seldom describe which criteria patients should apply when thinking critically about health information (15). Critical thinking is also a key component of evidence-based practice. As in health literacy studies, critical thinking in evidence-based practice is content specific, but is operationalised as practical skills such as the ability to formulate questions, find relevant research, and assess the certainty of research evidence using explicit criteria (15, 18, 19).

Efforts to promote critical thinking as a component of evidence-based practice have largely focussed on health professionals. However, interest in helping patients and the public to make evidence-informed decisions is growing (11). One such initiative is the [Informed Healthcare Choices](#) (IHC) project, which aims to help people to assess treatment claims and make informed health choices. The project has developed primary school resources and a podcast series to improve the ability of children and their

1
2
3 parents to assess claims about treatment effects. We have piloted these resources in Uganda, Kenya,
4
5 Rwanda, and Norway. We will test the effects of the resources in randomized trials in Uganda (20, 21).
6
7

8 *The Claim Evaluation Tools database*

9

10 The first step in the IHC project was to identify the Key Concepts people need to know to be able to
11 assess treatment effects (22). This resulted in an initial list of 32 Key Concepts that serves as a syllabus
12 for designing learning resources (22). This was also the starting point for the IHC learning resources. We
13 present a short list of the Key Concepts in table 1. This list is hosted by testingtreatments.org, and is an
14 evolving document subject to annual revisions.
15
16
17
18

19 Looking for suitable measurement tools to be used in the IHC trials, we conducted a systematic mapping
20 review of interventions and assessment tools addressing the Key Concepts (15). Based on the findings of
21 this review, we concluded that this research is heterogeneous and that outcomes are measured
22 inconsistently (15). Furthermore, we found no instrument that addressed all the Key Concepts, or that
23 would be suitable as an outcome measure in trials of the IHC learning resources. We therefore
24 developed a database of multiple-choice items that could be used outcome measures in the two IHC
25 trials in Uganda, as well for other purposes. The Claim Evaluation Tools database includes four or more
26 items that address each of the Key Concepts. We developed these items in four steps, using qualitative
27 and quantitative methods, over a three year period (2013-2016) (23):
28
29
30
31
32
33
34

- 35 (i) Determination of the scope of the database, writing and revising items;
- 36 (ii) Expert item review and feedback (face validity);
- 37 (iii) Cognitive interviews with end-users - including children, parents, teachers and patient
38 representatives - to assess relevance, understanding and acceptability; and
- 39 (iv) Piloting and practical administrative tests of the items in different contexts.
40
41
42
43
44

45 Instead of a standard, fixed questionnaire, we wanted to create a database from which teachers and
46 researchers can choose items relevant to their purposes and target groups, and design their own tests
47 or questionnaires (23). We developed all items in English, but translations are now also available in
48 Luganda (Uganda), Norwegian, German, Spanish (Mexico), and Chinese. Currently, the database includes
49 approximately 190 items. The items are designed to be relevant across different contexts, and can be
50 used for children (from ages 10 and up) and adults (including both patients and health professionals)
51 (23). We use “one-best answer” response options in all items, with one answer being unambiguously
52
53
54
55
56
57
58
59
60

the “best” and the remaining options “worse” (see figure 1 for an example of a multiple-choice item) (24).

We describe the development of the items in more detail elsewhere (23). We describe here the first psychometric testing, using Rasch analysis, of items from the Claim Evaluation Tools database. The items were selected for use in an outcome measure for trials of the IHC primary school resources and podcast. The purpose of the Rasch analysis is to ensure the validity and reliability of the outcome measure (25).

Table 1. Key Concepts that people need to understand to assess claims about treatment effects

Informed Health Choices Concepts
1. Recognising the need for fair comparisons of treatments <i>[Fair treatment comparisons are needed]</i>
1.1 Treatments may be harmful <i>[Treatments can harm]</i>
1.2 Personal experiences or anecdotes (stories) are an unreliable basis for determining the effects of most treatments <i>[Anecdotes are not reliable evidence]</i>
1.3 A treatment outcome may be associated with a treatment, but not caused by the treatment <i>[Association is not necessarily causation]</i>
1.4 Widely used or traditional treatments are not necessarily beneficial or safe <i>[Practice is often not based on evidence]</i>
1.5 New, brand-named, or more expensive treatments may not be better than available alternatives <i>[New treatments are not always better]</i>
1.6 Opinions of experts or authorities do not alone provide a reliable basis for deciding on the benefits and harms of treatments <i>[Expert opinion is not always right]</i>
1.7 Conflicting interests may result in misleading claims about the effects of treatments <i>[Be aware of conflicts of interest]</i>
1.8 Increasing the amount of a treatment does not necessarily increase the benefits of a treatment and may cause harm <i>[More is not necessarily better]</i>

1	
2	
3	
4	1.9 Earlier detection of disease is not necessarily better
5	<i>[Earlier is not necessarily better]</i>
6	
7	1.10 Hope can lead to unrealistic expectations about the effects of treatments
8	<i>[Avoid unrealistic expectations]</i>
9	
10	
11	1.11 Beliefs about how treatments work are not reliable predictors of the actual effects of treatments
12	<i>[Theories about treatment can be wrong]</i>
13	
14	1.12 Large, dramatic effects of treatments are rare
15	<i>[Dramatic treatment effects are rare]</i>
16	
17	
18	
19	
20	
21	2. Judging whether a comparison of treatments is a fair comparison
22	<i>[Treatment comparisons should be fair]</i>
23	
24	2.1 Evaluating the effects of treatments requires appropriate comparisons
25	<i>[Treatment comparisons are necessary]</i>
26	
27	
28	2.2 Apart from the treatments being compared, the comparison groups need to be similar (i.e. 'like needs to be compared with like')
29	<i>[Compare like with like]</i>
30	
31	
32	2.3 People's experiences should be counted in the group to which they were allocated
33	<i>[Base analyses on allocated treatment]</i>
34	
35	
36	2.4 People in the groups being compared need to be cared for similarly (apart from the treatments being compared)
37	<i>[Treat comparison groups similarly]</i>
38	
39	
40	2.5 If possible, people should not know which of the treatments being compared they are receiving
41	<i>[Blind participants to their treatments]</i>
42	
43	
44	2.6 Outcomes should be measured in the same way (fairly) in the treatment groups being compared
45	<i>[Assess outcome measures fairly]</i>
46	
47	
48	2.7 It is important to measure outcomes in everyone who was included in the treatment comparison groups
49	<i>[Follow up everyone included]</i>
50	
51	
52

<p>3.1 Small studies in which few outcome events occur are usually not informative and the results may be misleading <i>[Small studies may be misleading]</i></p>
<p>3.2 The use of p-values to indicate the probability of something having occurred by chance may be misleading; confidence intervals are more informative <i>[P-values alone can be misleading]</i></p>
<p>3.3 Saying that a difference is statistically significant or that it is not statistically significant can be misleading <i>['Significance' may be misleading]</i></p>
<p>4. Considering all of the relevant fair comparisons <i>[Consider all the relevant evidence]</i></p>
<p>4.1 The results of single tests of treatments can be misleading <i>[Single studies can be misleading]</i></p>
<p>4.2 Reviews of treatment tests that do not use systematic methods can be misleading <i>[Unsystematic reviews can mislead]</i></p>
<p>4.3 Well done systematic reviews often reveal a lack of relevant evidence, but they provide the best basis for making judgements about the certainty of the evidence <i>[Consider how certain the evidence is]</i></p>
<p>5. Understanding the results of fair comparisons of treatments <i>[Understand the results of comparisons]</i></p>
<p>5.1 Treatments may have beneficial and harmful effects <i>[Weigh benefits and harms of treatment]</i></p>
<p>5.2 Relative effects of treatments alone can be misleading <i>[Relative effects can be misleading]</i></p>
<p>5.3 Average differences between treatments can be misleading <i>[Average differences can be misleading]</i></p>
<p>6. Judging whether fair comparisons of treatments are relevant <i>[Judge relevance of fair comparisons]</i></p>

6.1 Fair comparisons of treatments should measure outcomes that are important <i>[Outcomes studied may not be relevant]</i>
6.2 Fair comparisons of treatments in animals or highly selected groups of people may not be relevant <i>[People studied may not be relevant]</i>
6.3 The treatments evaluated in fair comparisons may not be relevant or applicable <i>[Treatments used may not be relevant]</i>
6.4 Results for a selected group of people within fair comparisons can be misleading <i>[Beware of subgroup analyses]</i>

Please enter figure 1. Example of a multiple choice-item taken from the Claim Evaluation Tools database

Objective

To assess the validity, reliability, and responsiveness of multiple-choice items from the Claim Evaluation Tools database, using Rasch analysis, in English speaking populations in Uganda and Norway.

Methods

Scope and setting

Most of the data collection took place in Uganda. The reason for this was that we intended to use the items from the Claim Evaluation Tools database as the primary outcome measure for the IHC trials there. The items in the Claim Evaluation tools database are expected to work in the same way for children and adults (23). Consequently, for this evaluation, we needed a sample including both children and adults to explore item bias (differential item functioning) associated with age. We also needed a mix of people with and without relevant training. For these purposes, we invited children (in year-5 of primary school, with a starting age of 10 years) and adults who had participated in piloting of the IHC resources. We also recruited children, parents and other adults (without training) through our networks in Uganda established at the start of the IHC project (26, 27).

We also included a group of children who had participated in a pilot of the IHC primary school resources at an international school in Norway. Although this was a small sample, it provided an indication of the

1
2
3 fit to the Rasch model in an international population, and provide information on difficulty and
4 differential item functioning in the two different settings.
5
6
7
8
9

10 **Test administration and sample size**

11
12 We evaluated 88 items addressing the 22 Key Concepts initially targeted by two IHC interventions (26,
13 27). Having multiple items for each concept allows us to delete items with poor fit to the Rasch model.
14 In addition, Rasch analysis provides information on each item's difficulty. Having a range of items with
15 different difficulties addressing each Key Concept can be useful for measurement purposes, for example
16 when used in Computer Adaptive Testing.
17
18
19
20

21
22 There is no consensus on the sample size needed to perform a Rasch analysis (28). This is a pragmatic
23 judgement that takes account of the number of items evaluated and the statistical power needed to
24 identify item bias resulting from relevant background factors. Since we intended to test many items, we
25 did not consider it feasible to include these in a single test, and split the items into four sets or "tests".
26 We aimed to include approximately 250 respondents in Uganda for each of the four tests.
27
28
29
30

31
32 The children in Norway only responded to one set (out of the four). In both settings, we administered
33 the items in English, since this was the official school language in both the Norwegian international
34 school and the Ugandan schools. The data collection took place in 2015.
35
36
37

38 In developing the Claim Evaluation Tools database, low literacy skills were identified as a potential
39 barrier in the Ugandan setting (23). Consequently, we developed four items to evaluate the respondents'
40 text recognition and understanding as an indication of their reading ability (see Appendix 1). We
41 designed the items to resemble the multiple-choice items addressing the Key Concepts. The first two
42 items required the respondents to identify the correct text in the scenario. The latter two items
43 assessed whether the respondent understood the information in the scenario.
44
45
46
47
48
49
50

51 **Rasch analysis**

52
53
54 Rasch analysis is used to check the degree to which scoring and summing-up across items is defensible
55 in the data collected (29, 30). It is a unified approach to address important measurement issues required
56
57
58
59
60

1
2
3 for validating an outcome measure such as a scale or a test, including testing for; internal construct
4 validity (by testing for multidimensionality), invariance of the items (item-person-interaction), and item
5 bias (differential item function)(30).
6
7

8
9 Rasch analysis has been used successfully in many disciplines including health research, and can be
10 applied to both dichotomous and polytomous data (30-32). Rasch analysis also provides an excellent
11 basis for developing and revising items, and in construction of item banks. Misfit to the Rasch model
12 might be diagnosed and items can be deleted or revised to improve model fit (33). In this way, Rasch
13 analysis represents a dynamic approach to achieving construct validity, in which revisions are informed
14 by the evidence (33). For this analysis, we scored all items dichotomously. We used Excel for data entry,
15 RUMM2030 for Rasch analysis and SPSS for a simple classical test theory approach to distractor analysis.
16 We report the steps we took in our analysis below following the fundamental aspects of Rasch analysis
17 (30).
18
19
20
21
22
23
24
25
26
27

28 **Summary statistics and overall fit**

29
30
31 In Rasch analysis, the response patterns to an item set are tested against what is expected by the model,
32 i.e. the ratio between any two items should be constant across different ability groups (30). For this
33 study, ability refers to the “ability to critically assess claims about treatment effects” In other words, the
34 easier the item is, the more likely it will be answered correctly; and the more able the person is, the
35 more likely he or she will answer correctly (34). We explored this relationship between the expected and
36 observed data using the summary statistics function in RUMM2030.
37
38
39
40
41

42 The overall Item-Person Interaction is presented on a logit scale, where the mean item location is always
43 given as a zero. The mean person location is relative to the mean item location, and a mean person
44 location higher than and a mean person location higher or lower than “0” indicates that the test, on
45 average, is “too easy” or “too hard”, respectively.
46
47
48

49 From this analysis, we also report the item and person Fit Residual Statistics; this assesses the degree of
50 divergence (or residual) between the expected and observed data for each person item when summed
51 for all items and all persons respectively. In RUMM2030 this is reported as an approximate z-score,
52
53
54
55
56
57

1
2
3 representing a standardized normal distribution (35). Ideally, item fit and person fit should have a mean
4 of zero and a SD of one (30).
5
6

7
8 The Item-Trait- Interaction is an overall test of invariance to the set of items, and the extent to which
9 the items are working as expected at the grouped ability levels (36). This is represented as a Chi-Square
10 probability value. Ideally, this should be greater than 0.05, indicating that there is no “statistically
11 significant” deviation between the observed and “expected” data.
12
13

14 15 16 17 18 **Power of test of fit and reliability**

19
20 The Person-Separation Index is an indicator of the power of a set of items to discriminate between
21 ability groups (35). We considered a Person-Separation-Index greater than 0.7 to be acceptable (35). We
22 also calculated Cronbach’s Alpha as a measure of the reliability of each set of items. We considered a
23 value of 0.7 or higher to be adequate for this. Cronbach’s Alpha is only available if there are no missing
24 data. We solved this by calculating missing responses as “incorrect” responses (35).
25
26
27
28
29
30
31

32 **Individual person and item fit**

33
34
35 We investigated individual person fit. Misfit violates the principles of the Guttman structure and may
36 indicate different types of error, such as guessing.
37
38

39
40 The Item Characteristic Curve indicates the Rasch model’s theoretically expected probability of
41 answering correctly as a function of ability on the latent trait scale (see Figure 2 for an example of an
42 Item Characteristic Curve). We inspected Item Characteristic Curves and used chi-square values as single
43 item fit indices using a $p = 5\%$ as our significance level. Using Bonferroni adjustment, the significance
44 level was adjusted ($p = 0.05/k$) according to the number of k significance tests carried out (one for each
45 item).
46
47
48
49

50
51 We also performed distractor analysis using SPSS. The latter is particularly useful in developing and
52 revising multiple-choice items, because it may identify response options (distractors) that are not
53 working as intended and can subsequently be deleted or revised.
54
55
56
57

1
2
3
4
5
6 Please insert figure 2. The Item Characteristic Curve
7
8
9
10

11 The curve in figure 2 represents the expected probability of answering correctly, and the dots represent
12 the observed proportion of correct answers for some intervals of ability estimates (class intervals).

13 When the observed proportions fit the curve, the data fit the Rasch model. Items with sub-optimal fit
14 indicate measurement error (35).
15
16
17

18 When two groups of people (for example children and adults) respond differently to an item despite
19 equal ability levels, that item displays “within item bias” or differential item functioning (DIF) and
20 invariance is violated (37). We explored DIF using ANOVA in RUMM2030. There are two types of DIF.
21 Uniform DIF is when one group of people perform consistently better on an item; for example, when an
22 item is easier for all adults across all ability groups compared to children. This is less problematic than
23 non-uniform DIF, where the differences between the groups vary across levels of the attribute (30).
24
25
26
27
28
29
30
31
32

33 **Testing for multidimensionality and response dependency**

34
35 Unidimensionality - having just one trait underlying respondents’ responses - is a fundamental
36 requirement of measurement and is explored using Rasch analysis (34). Furthermore, there should be
37 no response dependency in the data; i.e. people’s responses to an item should not have a bearing on
38 their responses to other items (38). Response dependence results in redundancy in the data and
39 inefficient measures.
40
41
42
43

44 We explored possible dimension violations of local independence applying the PCA/t-test procedure
45 computing paired t-tests using two sub-sets of items from each item set. The hypothesis of a
46 unidimensional scale is weakened when the proportion of individuals with statistically significant
47 differences in ability estimates on a pair of subscales exceeds 5% (39). We also inspected the residual
48 correlation matrix estimated in RUMM2030 (40). We considered residual correlations above 0.3 as
49 indicators of response dependence between items (41).

Results

Description of sample

The total sample included 1114 people, among whom 685 were children and 429 were adults (including 171 health professionals). Of these 1114 people, 329 had received some form of training related to the Key Concepts. The Norwegian sample equalled 5% (59 respondents) out of the total respondents. The mean number of missing and incorrectly filled in responses was <1% per item set. Less than 1/3 responded correctly to all four reading test questions in the Ugandan sample, indicating a low literacy level in English.

Summary statistics and overall fit

Overall, the items were difficult with no very easy items and no extremely difficult items (see figure 2 for the Item Threshold distributions per set). The mean person locations per set were -0.81, -1.06, -1.15 and -1.15 logits, respectively. Fit Statistics are presented in table 2. Mean item fit residuals and person fit residuals were satisfactory and close to 0, although the standard errors for set 1 and 2 is somewhat higher than what we would like to see. The Item-Person maps for all sets are available in figures 3 to 6. The upper part of the Item-Person map represents respondents' ability levels; the lower part show the distribution of item locations. From this we can see that overall the items are difficult, suggesting that items with lower difficulties might be needed to make these tests more sensitive (able to discriminate between people at the lower end of the scale (those with lower ability) (35). The item-Trait interaction had a Chi square probability of 0.00 for all sets, indicating that not all items may work as expected.

The estimated reliability indices were also acceptable (Cronbach's Alpha > 0.70 for all sets with exception of set 4 where the value was 0.63). Similarly, the Person-Separation Indexes were satisfactory for all sets with the exception of set 4 which had a value of 0.54.

Please enter figure 5. Item Person map for item set 3

Please enter figure 6. Item Person map for item set 4

Individual person and item fit

We identified few persons with misfit. Likewise, we identified only two items with potential misfit in set 1, and one item in the remaining three sets (see table 2).

Overall, most items fit well to the Rach model. However, out of the 88 items, seventeen items were found to have poor model fit. The findings resulting from the distractor analyses, also suggested that many of the items would be improved by deleting or revising response options.

1
2
3 In set 1 (the only set applied in both Uganda and Norway), five items displayed uniform DIF and one
4 item displayed non-uniform DIF associated with setting (i.e., Norway and Uganda). Across the four sets,
5 six items displayed uniform DIF associated with age.
6
7
8
9

10 **Multidimensionality and response dependency**

11 We did not observe any statistically significant residual correlation between pairs of items, and the
12 paired *t*-test procedure indicated that the sets were sufficiently unidimensional (Table 2).
13
14
15
16

17 **Discussion**

18 We have developed the Claim Evaluation Tools database using qualitative and quantitative feedback
19 from methodologists and end-users in six countries (23). This study reports the findings of the first
20 psychometric testing of multiple-choice items from the database, using Rasch analysis conducted in two
21 settings, Uganda and Norway.

27
28

29 Most of the 88 items (addressing 22 Key Concepts) conformed well to the Rasch model. However some
30 items displayed DIF by setting and age, and some items required revisions. Overall, we found that the
31 four item sets created from the Claim Evaluation Tools database had acceptable reliability. We did not
32 identify significant response dependence between any pairs of items and, overall, the magnitude of
33 multidimensionality in the data was acceptable.
34
35
36
37
38

39 Feedback on the items from experts and end-users suggested that the items were difficult (23). The
40 Rasch analyses confirmed this. Moreover, the respondents reading skills were found to be low in the
41 target population in Uganda. This suggests that efforts should be made to simplify the text in the
42 scenarios and editing the response options to improve readability and improve validity. Reducing the
43 number of response options in the items could also contribute to making the items less difficult.
44
45
46
47
48

49 Based on the findings from our analyses, we decided to remove items with non-uniform DIF from the
50 Claim Evaluation Database. We also decided to revise items with poor model fit and reduce response
51 options that did not work as expected. Revised items will be retested in the Ugandan context, where
52 they will be used as an outcome measure.
53
54
55
56
57

1
2
3
4
5 A limitation of this study is that we tested the items in only two settings, Uganda and Norway, and that
6 the fit to the Rasch model in other settings is unknown. Further testing of items from the Claim
7 Evaluation Tools database using Rasch Analysis in other countries and languages is needed. We also did
8 not include the respondents' gender in the analysis, which could introduce further DIF. This will be
9 explored in further testing.
10
11
12

13
14
15 There has been an encouraging interest in the Claim Evaluation Tools database in settings other than the
16 countries included in the IHC project, and researchers in Norway, Mexico, Germany and China are
17 currently translating and testing the multiple-choice items in their settings. In addition, the items
18 addressing the Key Concepts we judged to be more advanced, and which were not tested as part of this
19 study, are currently being tested online through www.testingtreatments.org, targeting people with
20 relevant training, such as health researchers or teachers of evidence-based medicine. We are also
21 developing items to assess intended behaviours and attitudes towards assessing treatment claims. The
22 Claim Evaluation Tools database, which includes all of these questions, as well as findings from
23 evaluations such as this one, is freely available for non-commercial use on request through the Testing
24 Treatments interactive website (www.testingtreatments.org).
25
26
27
28
29
30
31
32
33

34 When used for evaluating peoples' ability to assess treatment claims, an item set generated from the
35 Claim Evaluation Tools database can be scored by calculating the number or percentage of correct
36 responses. However, such scores can be difficult to interpret, especially when comparing the average
37 score of two groups (e.g. in a randomised trial). An absolute (criterion referenced) standard for a passing
38 score (i.e. a cut-off for passing) or for mastery of the Key Concepts that are tested. Setting a cut-off
39 requires judgement, and there are several ways of doing this (42-44). For the items that will be used in
40 the trials of the IHC primary school resources and podcast, we have established criteria referenced
41 standards using a combination of Nedelsky's and Angoff's methods (42-45).
42
43
44
45
46
47
48
49

50 Conclusion

51
52 We found that most items that we tested had satisfactory fit to the Rasch model. Taken together with
53 our previously reported findings, the findings of this study suggest that the items have face and
54 construct validity in the settings in which they have been tested. Following revisions of some items,
55
56
57
58
59
60

1
2
3 informed by the findings from this study, most of the items that we tested are suitable for use in an
4
5 outcome measure that evaluates people's ability to apply the key concepts they need to know to be able
6
7 to assess treatment claims.
8
9

10 11 12 **Authors' contributions**

13
14
15 AA, ØG, AO wrote the protocol and the IHC group provided comments to this protocol. The Claim
16
17 Evaluation Tools database was developed by the IHC group. AA coordinated all of the development and
18
19 evaluation process with support from AO. DS, AN and KO performed the data collection and data entry
20
21 from the field-testing. ØG and AA prepared the data files for the analysis, and ØG conducted the Rasch
22
23 analyses. AA authored this manuscript with significant input from the IHC group.
24
25
26

27 **Acknowledgements**

28
29
30 We are deeply grateful to all of the enthusiastic children, parents and teachers that contributed to this
31
32 project. We would also like to thank the IHC advisory panel, and the other researchers and
33
34 methodologists that provided their advice in the development process.
35
36
37

38 **Funding and competing interests**

39
40 The IHC project is funded by the Research Council of Norway- GLOBVAC project 220603. The authors
41
42 declare no conflicting interests.
43
44
45

46 **Ethical approval**

47
48 The research was approved by the Makerere University School of Medicine Research and Ethics
49
50 Committee and the Uganda National Council for Science and Technology.

21. A review summarized studies comparing playing sports with other ways of making people happy. The review authors included all studies that found that sports improve people's happiness. Based on these studies, the review authors said that sport definitely improves happiness.

Question: **Do you agree with what the review authors said?**

Options:

- A) It is not possible to say without knowing the opinion of sports experts
- B) No. The review authors included only those studies with favorable results
- C) Yes. The review authors were sure that sports improves happiness
- D) Yes, the review authors included all of the studies with favorable results

Answer:

1. A doctor did a study to find out if drinking tea keeps people from getting sick. The doctor tossed a coin to decide who should get the tea and who should not. People who got tea went to the doctor's office every day to drink their tea. At the end of the study, people who got the tea were less likely to be sick than those who got no tea.

Based on the text above, please answer the following questions:

1.1 Who went to the doctor's office every day?

Options:

- A) People who did not get tea
- B) People who got tea
- C) Everyone
- D) People who got sick

Answer:

1.2. How did the doctor decide who should get tea?

Options:

- A) By tossing a coin
- B) By asking people what they would like
- C) They gave tea to those who were more likely to be sick
- D) They asked people who came to their office

1.4. What was the result of the study?

Options:

- A) Drinking tea can help people from getting sick
- B) Doctors should toss coins when doing studies
- C) People should go to the doctor if they are sick
- D) Not drinking tea can help people from getting sick

Answer:

BMJ Open

Measuring ability to assess claims about treatment effects: A latent trait analysis of items from the "Claim Evaluation Tools" database using Rasch modelling

Journal:	<i>BMJ Open</i>
Manuscript ID	bmjopen-2016-013185.R2
Article Type:	Research
Date Submitted by the Author:	10-Mar-2017
Complete List of Authors:	Austvoll-Dahlgren, Astrid; Norwegian Institute of Public Health Guttersrud, Øystein; Norwegian Centre for Science Education, University of Oslo Nsangi, Allen; Makerere University College of Health Sciences, School of Medicine Semakula, Daniel; Makerere University College of Health Sciences, Oxman, Andrew; Norwegian Institute of Public Health
Primary Subject Heading:	Patient-centred medicine
Secondary Subject Heading:	Research methods, Public health, Health policy

56

Abstract

Background: The Claim Evaluation Tools database contains multiple-choice items for measuring people's ability to apply the key concepts they need to know to be able to assess treatment claims. We assessed items from the database using Rasch analysis to develop an outcome measure to be used in two randomised trials in Uganda. Rasch analysis is a form of psychometric testing relying on Item Response Theory. It is a dynamic way of developing outcome measures that are valid and reliable.

Objectives: To assess the validity, reliability, and responsiveness of 88 items addressing 22 key concepts using Rasch analysis.

Participants: We administered four sets of multiple-choice items in English to 1114 people in Uganda and Norway, of which 685 were children and 429 were adults (including 171 health professionals). We scored all items dichotomously. We explored summary and individual fit statistics using the RUMM2030 analysis package. We used SPSS to perform distractor analysis.

Results: Most items conformed well to the Rasch model but some items needed revision. Overall, the four item sets had satisfactory reliability. We did not identify significant response dependence between any pairs of items and, overall, the magnitude of multidimensionality in the data was acceptable. The items had a high level of difficulty.

Conclusion: Most of the items conformed well to the Rasch model's expectations. Following revision of some items, we concluded that most of the items were suitable for use in an outcome measure for evaluating the ability of children or adults to assess treatment claims.

Strengths and limitations of this study

- To our knowledge, this is the first Rasch analysis of multiple-choice items that measure people's ability to assess claims about treatment effects.
- We have used robust methods to evaluate the items' validity and reliability in two settings, allowing for evidence informed revisions.
- Our analyses suggest that most items have acceptable model fit and can be used in the settings where they were tested.
- The items might function differently when translated or used in other settings.

For peer review only

Background

People are confronted with claims about treatment effects daily. This includes claims about the effects of changes in health behaviour, screening, other preventive interventions, therapeutic interventions, rehabilitation, and public health and health system interventions that are targeted at groups of people. A “treatment claim” is something someone says about whether a treatment causes something to happen or to change; for example, that Vitamin C prevents you from getting the common cold. A claim can be true or can be false (1-4). Many of these claims are not based on evidence from fair comparisons of treatments, and many patients and health professionals alike do not have the necessary skills to assess the reliability of these claims (5-11). Being able to think critically and make informed decisions is essential for engaging patients in clinical decisions and citizens in policy decisions (10, 12-14).

Interest in promoting critical thinking cuts across disciplines (15). There are many definitions and conceptualisations of critical thinking. In the learning sciences, critical thinking is defined as “purposeful, self-regulatory judgment that results in interpretation, analysis, evaluation, and inference, as well as explanations of the considerations on which that judgment is based” (16). There is debate about the extent to which critical thinking skills are “generic” and the extent to which they are content specific. Critical thinking is also a component of health literacy (17). In health literacy studies, critical thinking is content specific, focussing on people’s ability to think critically about health information. However, definitions of this component of health literacy are often fuzzy. They seldom describe which criteria patients should apply when thinking critically about health information (15). Critical thinking is also a key component of evidence-based practice. As in health literacy studies, critical thinking in evidence-based practice is content specific, but is operationalised as practical skills such as the ability to formulate questions, find relevant research, and assess the certainty of research evidence using explicit criteria (15, 18, 19).

Efforts to promote critical thinking as a component of evidence-based practice have largely focussed on health professionals. However, interest in helping patients and the public to make evidence-informed decisions is growing (11). One such initiative is the [Informed Healthcare Choices](#) (IHC) project, which aims to help people to assess treatment claims and make informed health choices. The project has developed primary school resources and a podcast series to improve the ability of children and their

parents to assess claims about treatment effects. We have piloted these resources in Uganda, Kenya, Rwanda, and Norway. We will test the effects of the resources in randomized trials in Uganda (20, 21).

The Claim Evaluation Tools database

The first step in the IHC project was to identify the Key Concepts people need to know to be able to assess treatment effects (22). This resulted in an initial list of 32 Key Concepts that serves as a syllabus for designing learning resources (22). This was also the starting point for the IHC learning resources. We present a short list of the Key Concepts in table 1. This list is hosted by testingtreatments.org, and is an evolving document subject to annual revisions.

Looking for suitable measurement tools to be used in the IHC trials, we conducted a systematic mapping review of interventions and assessment tools addressing the Key Concepts (15). Based on the findings of this review, we concluded that this research is heterogeneous and that outcomes are measured inconsistently (15). Furthermore, we found no instrument that addressed all the Key Concepts, or that would be suitable as an outcome measure in trials of the IHC learning resources. We therefore developed a database of multiple-choice items that could be used outcome measures in the two IHC trials in Uganda, as well for other purposes. The Claim Evaluation Tools database includes four or more items that address each of the Key Concepts. We developed these items in four steps, using qualitative and quantitative methods, over a three year period (2013-2016) (23):

- (i) Determination of the scope of the database, writing and revising items;
- (ii) Expert item review and feedback (face validity);
- (iii) Cognitive interviews with end-users - including children, parents, teachers and patient representatives - to assess relevance, understanding and acceptability; and
- (iv) Piloting and practical administrative tests of the items in different contexts.

Instead of a standard, fixed questionnaire, we wanted to create a database from which teachers and researchers can choose items relevant to their purposes and target groups, and design their own tests or questionnaires (23). We developed all items in English, but translations are now also available in Luganda (Uganda), Norwegian, German, Spanish (Mexico), and Chinese. Currently, the database includes approximately 190 items. The items are designed to be relevant across different contexts, and can be used for children (from ages 10 and up) and adults (including both patients and health professionals) (23). We use “one-best answer” response options in all items, with one answer being unambiguously

the “best” and the remaining options “worse” (see figure 1 for an example of a multiple-choice item) (24).

We describe the development of the items in more detail elsewhere (23). We describe here the first psychometric testing, using Rasch analysis, of items from the Claim Evaluation Tools database. The items were selected for use in an outcome measure for trials of the IHC primary school resources and podcast. The purpose of the Rasch analysis is to ensure the validity and reliability of the outcome measure (25).

Table 1. Key Concepts that people need to understand to assess claims about treatment effects

Informed Health Choices Concepts
1. Recognising the need for fair comparisons of treatments <i>[Fair treatment comparisons are needed]</i>
1.1 Treatments may be harmful <i>[Treatments can harm]</i>
1.2 Personal experiences or anecdotes (stories) are an unreliable basis for determining the effects of most treatments <i>[Anecdotes are not reliable evidence]</i>
1.3 A treatment outcome may be associated with a treatment, but not caused by the treatment <i>[Association is not necessarily causation]</i>
1.4 Widely used or traditional treatments are not necessarily beneficial or safe <i>[Practice is often not based on evidence]</i>
1.5 New, brand-named, or more expensive treatments may not be better than available alternatives <i>[New treatments are not always better]</i>
1.6 Opinions of experts or authorities do not alone provide a reliable basis for deciding on the benefits and harms of treatments <i>[Expert opinion is not always right]</i>
1.7 Conflicting interests may result in misleading claims about the effects of treatments <i>[Be aware of conflicts of interest]</i>
1.8 Increasing the amount of a treatment does not necessarily increase the benefits of a treatment and may cause harm <i>[More is not necessarily better]</i>

1	
2	
3	
4	1.9 Earlier detection of disease is not necessarily better
5	<i>[Earlier is not necessarily better]</i>
6	
7	1.10 Hope can lead to unrealistic expectations about the effects of treatments
8	<i>[Avoid unrealistic expectations]</i>
9	
10	1.11 Beliefs about how treatments work are not reliable predictors of the actual effects of treatments
11	<i>[Theories about treatment can be wrong]</i>
12	
13	
14	1.12 Large, dramatic effects of treatments are rare
15	<i>[Dramatic treatment effects are rare]</i>
16	
17	
18	
19	
20	2. Judging whether a comparison of treatments is a fair comparison
21	<i>[Treatment comparisons should be fair]</i>
22	
23	2.1 Evaluating the effects of treatments requires appropriate comparisons
24	<i>[Treatment comparisons are necessary]</i>
25	
26	
27	2.2 Apart from the treatments being compared, the comparison groups need to be similar (i.e. 'like needs to be compared with like')
28	<i>[Compare like with like]</i>
29	
30	
31	
32	2.3 People's experiences should be counted in the group to which they were allocated
33	<i>[Base analyses on allocated treatment]</i>
34	
35	
36	2.4 People in the groups being compared need to be cared for similarly (apart from the treatments being compared)
37	<i>[Treat comparison groups similarly]</i>
38	
39	2.5 If possible, people should not know which of the treatments being compared they are receiving
40	<i>[Blind participants to their treatments]</i>
41	
42	
43	2.6 Outcomes should be measured in the same way (fairly) in the treatment groups being compared
44	<i>[Assess outcome measures fairly]</i>
45	
46	
47	2.7 It is important to measure outcomes in everyone who was included in the treatment comparison groups
48	<i>[Follow up everyone included]</i>
49	
50	
51	
52	
53	3. Understanding the role of chance
54	<i>[Understand the role of chance]</i>
55	
56	
57	
58	
59	
60	

1	
2	
3	
4	3.1 Small studies in which few outcome events occur are usually not informative and the results may be misleading
5	<i>[Small studies may be misleading]</i>
6	
7	3.2 The use of p-values to indicate the probability of something having occurred by chance may be misleading; confidence
8	intervals are more informative
9	<i>[P-values alone can be misleading]</i>
10	
11	3.3 Saying that a difference is statistically significant or that it is not statistically significant can be misleading
12	<i>['Significance' may be misleading]</i>
13	
14	
15	
16	
17	
18	4. Considering all of the relevant fair comparisons
19	<i>[Consider all the relevant evidence]</i>
20	
21	4.1 The results of single tests of treatments can be misleading
22	<i>[Single studies can be misleading]</i>
23	
24	
25	4.2 Reviews of treatment tests that do not use systematic methods can be misleading
26	<i>[Unsystematic reviews can mislead]</i>
27	
28	4.3 Well done systematic reviews often reveal a lack of relevant evidence, but they provide the best basis for making
29	judgements about the certainty of the evidence
30	<i>[Consider how certain the evidence is]</i>
31	
32	
33	
34	
35	
36	5. Understanding the results of fair comparisons of treatments
37	<i>[Understand the results of comparisons]</i>
38	
39	5.1 Treatments may have beneficial and harmful effects
40	<i>[Weigh benefits and harms of treatment]</i>
41	
42	
43	5.2 Relative effects of treatments alone can be misleading
44	<i>[Relative effects can be misleading]</i>
45	
46	5.3 Average differences between treatments can be misleading
47	<i>[Average differences can be misleading]</i>
48	
49	
50	
51	
52	6. Judging whether fair comparisons of treatments are relevant
53	<i>[Judge relevance of fair comparisons]</i>
54	
55	
56	
57	
58	
59	
60	

6.1 Fair comparisons of treatments should measure outcomes that are important <i>[Outcomes studied may not be relevant]</i>
6.2 Fair comparisons of treatments in animals or highly selected groups of people may not be relevant <i>[People studied may not be relevant]</i>
6.3 The treatments evaluated in fair comparisons may not be relevant or applicable <i>[Treatments used may not be relevant]</i>
6.4 Results for a selected group of people within fair comparisons can be misleading <i>[Beware of subgroup analyses]</i>

Please enter figure 1. Example of a multiple choice-item taken from the Claim Evaluation Tools database

Objective

To assess the validity, reliability, and responsiveness of multiple-choice items from the Claim Evaluation Tools database, using Rasch analysis, in English speaking populations in Uganda and Norway.

Methods

Scope and setting

Most of the data collection took place in Uganda. The reason for this was that we intended to use the items from the Claim Evaluation Tools database as the primary outcome measure for the IHC trials there. The items in the Claim Evaluation tools database are expected to work in the same way for children and adults (23). Consequently, for this evaluation, we needed a sample including both children and adults to explore item bias (differential item functioning) associated with age. We also needed a mix of people with and without relevant training. For these purposes, we invited children (in year-5 of primary school, with a starting age of 10 years) and adults who had participated in piloting of the IHC resources. We also recruited children, parents and other adults (without training) through our networks in Uganda established at the start of the IHC project (26, 27).

We also included a group of children who had participated in a pilot of the IHC primary school resources at an international school in Norway. Although this was a small sample, it provided an indication of the

1
2
3 fit to the Rasch model in an international population, and provide information on difficulty and
4 differential item functioning in the two different settings.
5
6
7
8
9

10 **Test administration and sample size**

11
12 We evaluated 88 items addressing the 22 Key Concepts initially targeted by two IHC interventions (26,
13 27). Having multiple items for each concept allows us to delete items with poor fit to the Rasch model.
14 In addition, Rasch analysis provides information on each item's difficulty. Having a range of items with
15 different difficulties addressing each Key Concept can be useful for measurement purposes, for example
16 when used in Computer Adaptive Testing.
17
18
19
20

21
22 There is no consensus on the sample size needed to perform a Rasch analysis (28). This is a pragmatic
23 judgement that takes account of the number of items evaluated and the statistical power needed to
24 identify item bias resulting from relevant background factors. Since we intended to test many items, we
25 did not consider it feasible to include these in a single test, and split the items into four sets or "tests".
26 We aimed to include approximately 250 respondents in Uganda for each of the four tests.
27
28
29
30

31
32 The children in Norway only responded to one set (out of the four). In both settings, we administered
33 the items in English, since this was the official school language in both the Norwegian international
34 school and the Ugandan schools. The data collection took place in 2015.
35
36
37

38 In developing the Claim Evaluation Tools database, low literacy skills were identified as a potential
39 barrier in the Ugandan setting (23). Consequently, we developed four items to evaluate the respondents'
40 text recognition and understanding as an indication of their reading ability (see Appendix 1). We tested
41 these items using the Lexile Analyser, and the items were found to fit within typical reading measures
42 for 5th graders (29). We designed the items to resemble the multiple-choice items addressing the Key
43 Concepts. The first two items required the respondents to identify the correct text in the scenario. The
44 latter two items assessed whether the respondent understood the information in the scenario.
45
46
47
48
49
50
51
52

53 **Rasch analysis**

1
2
3 Rasch analysis is used to check the degree to which scoring and summing-up across items is defensible
4 in the data collected (30, 31). It is a unified approach to address important measurement issues required
5 for validating an outcome measure such as a scale or a test, including testing for; internal construct
6 validity for multidimensionality, invariance of the items (item-person-interaction), and item bias
7 (differential item function)(31).
8
9

10
11
12 Rasch analysis has been used successfully in many disciplines including health research, and can be
13 applied to both dichotomous and polytomous data (31-33). Rasch analysis also provides an excellent
14 basis for developing and revising items, and in construction of item banks. Misfit to the Rasch model
15 might be diagnosed and items can be deleted or revised to improve model fit (34). In this way, Rasch
16 analysis represents a dynamic approach to achieving construct validity, in which revisions are informed
17 by the evidence (34). For this analysis, we scored all items dichotomously. We used Excel for data entry,
18 RUMM2030 for Rasch analysis and SPSS for a simple classical test theory approach to distractor analysis.
19 We report the steps we took in our analysis below following the fundamental aspects of Rasch analysis
20 (31).
21
22
23
24
25
26
27
28
29
30
31

32 **Summary statistics and overall fit**

33
34 In Rasch analysis, the response patterns to an item set are tested against what is expected by the model,
35 i.e. the ratio between any two items should be constant across different ability groups (31). For this
36 study, ability refers to the “ability to critically assess claims about treatment effects”. In other words, the
37 easier the item is, the more likely it will be answered correctly; and the more able the person is, the
38 more likely he or she will answer correctly (35). We explored this relationship between the expected and
39 observed data using the summary statistics function in RUMM2030.
40
41
42
43
44

45 The overall Item-Person Interaction is presented on a logit scale, and in RUMM2030 the mean item
46 location is always given as a zero. A mean person location higher than “0” indicates that on average, the
47 test is “too easy” and that the response group have a higher ability than the difficult level of the test. A
48 mean person location lower than “0” suggests the test is “too hard”.
49
50
51
52

53 From this analysis, we also report the item and person Fit Residual Statistics; this assesses the degree of
54 divergence (or residual) between the expected and observed data for each person item when summed
55
56
57

1
2
3 for all items and all persons respectively. In RUMM2030 this is reported as an approximate z-score,
4 representing a standardized normal distribution (36). Ideally, item fit and person fit should have a mean
5 of zero and a SD of one (31).
6
7

8
9 The Item-Trait- Interaction in RUMM2030 is a test of invariance to the scale, and whether or not the
10 data fit the model for the discreet ability groups (37). Ideally, the Chi-Square probability value should be
11 greater than 0.05, indicating that there is no “statistically significant” deviation between the observed
12 data and what is expected from the model.
13
14
15

16 17 18 19 20 **Power of test of fit and reliability**

21
22 The Person-Separation Index is an indicator of the power of a set of items to discriminate between
23 ability groups and individuals (36). We considered a Person-Separation-Index greater than 0.7 to be
24 acceptable (36). We also calculated Cronbach’s Alpha as a measure of the reliability of each set of items.
25 We considered a value of 0.7 or higher to be adequate for this. In RUMM2030, Cronbach’s Alpha can
26 only be estimated if there are no missing data. We solved this by coding missing responses as “incorrect”
27 responses (36).
28
29
30
31
32
33
34
35

36 37 38 39 40 41 42 **Individual person and item fit**

43 We investigated individual person fit. Misfit violates the principles of the Guttman structure and may
44 indicate different types of error, such as guessing.

45 The Item Characteristic Curve indicates the theoretically expected probability of answering correctly as a
46 function of ability on the latent trait scale (see Figure 2 for an example of an Item Characteristic Curve).
47 We inspected Item Characteristic Curves and used Chi-square values as single item fit indices using a
48 0.05 as our significance level. Using Bonferroni adjustment, the significance level was adjusted ($p =$
49 $0.05/k$) according to the number of k significance tests carried out (one for each item).
50
51

52 We also performed distractor analysis using SPSS. This is particularly useful when developing and
53 revising multiple-choice items, because it may identify response options that are not working as
54 intended and can subsequently be deleted or revised.
55
56

1
2
3
4
5
6 Please insert figure 2. The Item Characteristic Curve
7
8
9

10
11 The curve in figure 2 represents the expected probability of answering correctly, and the dots represent
12 the observed proportion of correct answers for some intervals of ability estimates (class intervals).

13
14 When the observed proportions fit the curve, the data fit the Rasch model. Items with sub-optimal fit
15 indicate measurement error (36).
16

17
18
19 When two groups of people (for example children and adults) respond differently to an item despite
20 equal ability, that item displays “within item bias” or differential item functioning (DIF) and invariance is
21 violated (38). There are two types of DIF. Uniform DIF is when one group of people perform consistently
22 better on an item; for example, when an item is easier for all adults across all ability groups compared to
23 children. This is less problematic than non-uniform DIF, where the differences between the groups vary
24 across levels of the attribute (31).
25
26
27
28

29
30 We explored DIF for setting and age using ANOVA in RUMM2030. We also explored DIF by reading
31 ability. This was done by pragmatically categorising the responses to the four reading ability items into
32 two groups (merging respondents with 0, 1 or 2 correct responses and those with 3 or 4 correct
33 responses).
34
35
36
37
38
39

40 **Testing for multidimensionality and response dependency**

41
42 Unidimensionality - having just one trait underlying responses - is a fundamental requirement of
43 measurement and is explored using Rasch analysis (35). Furthermore, there should be no response
44 dependency in the data; i.e. people’s responses to an item should not have a bearing on their responses
45 to other items (39). Response dependence results in redundancy in the data and inefficient measures.
46
47
48

49
50 We explored possible dimension violations of local independence applying the PCA/t-test procedure
51 computing paired t-tests using two sub-sets of items from each item set. The hypothesis of a
52 unidimensional scale is weakened when the proportion of individuals with statistically significant
53 differences in ability estimates on a pair of subscales exceeds 5% (40). We also inspected the residual
54
55
56
57

1
2
3 correlation matrix estimated in RUMM2030 (41). We considered residual correlations above 0.3 as
4 indicators of response dependence between items (42).
5
6
7
8
9

10 **Results**

11 **Description of sample**

12
13
14 The total sample included 1114 people, among whom 685 were children and 429 were adults (including
15 171 health professionals). Of these 1114 people, 329 had received some form of training related to the
16 Key Concepts. The Norwegian sample equalled 5% (59 respondents) out of the total respondents. The
17 mean number of missing and incorrectly filled in responses was <1% per item set. Less than 1/3
18 responded correctly to all four reading test questions in the Ugandan sample.
19
20
21
22
23
24
25
26
27

28 **Summary statistics and overall fit**

29
30
31 Overall, the items were difficult with no very easy items and no extremely difficult items (see figure 2 for
32 the item threshold distributions per set). The mean person locations per set were -0.81, -1.06, -1.15 and
33 -1.15 logits, respectively. Fit Statistics are presented in table 2. Mean item fit residuals and person fit
34 residuals were satisfactory and close to 0, although the standard errors for set 1 and 2 is somewhat
35 higher than what we would like to see. The Item-Person maps for all sets are available in figures 3 to 6.
36 The upper part of the Item-Person map represents respondents' ability levels; the lower part show the
37 distribution of item locations. From this we can see that, overall, the tests are difficult. This suggests that
38 that easier items might be needed to make these tests more sensitive (able to separate between people
39 at the lower end of the scale (those with lower ability) (36). The Chi square probability was 0.00 for all
40 sets, indicating that not all items may work as expected.
41
42
43
44
45
46
47
48

49 The estimated reliability indices were acceptable (Cronbach's Alpha > 0.70 for all sets with exception of
50 set 4 where the value was 0.63). Similarly, the Person-Separation Indexes were satisfactory for all sets
51 with the exception of set 4 which had a value of 0.54.

Please enter figure 6. Item Person map for item set 4

Individual person and item fit

We identified few persons with misfit. Likewise, we identified only two items with potential misfit in set 1, and one item in the remaining three sets (see table 2).

1
2
3 Overall, most items fit well to the Rasch model. However, out of the 88 items, seventeen items were
4 found to have poor model fit. The findings resulting from the distractor analyses, also suggested that
5 many of the items would be improved by deleting or revising response options.
6
7

8
9 In set 1 (the only set applied in both Uganda and Norway), five items displayed uniform DIF and one
10 item displayed non-uniform DIF associated with setting (i.e., Norway and Uganda). Across the four sets
11 including 88 items, six items displayed uniform DIF associated with age, and 7 items indicated DIF
12 associated with reading ability.
13
14
15

16 17 18 19 **Multidimensionality and response dependency**

20 We did not observe any statistically significant residual correlation between pairs of items, and the
21 paired *t*-test procedure indicated that the sets were sufficiently unidimensional (Table 2).
22
23
24

25 26 27 **Discussion**

28 We have developed the Claim Evaluation Tools database using qualitative and quantitative feedback
29 from methodologists and end-users in six countries (23). This study reports the findings of the first
30 psychometric testing of multiple-choice items from the database, using Rasch analysis conducted in two
31 settings, Uganda and Norway.
32
33
34
35

36 Most of the 88 items (addressing 22 Key Concepts) conformed well to the Rasch model. However some
37 items displayed DIF and required revisions. Overall, we found that the four item sets created from the
38 Claim Evaluation Tools database had acceptable reliability. We did not identify significant response
39 dependence between any pairs of items and, the magnitude of multidimensionality in the data was
40 acceptable.
41
42
43
44
45

46 Based on findings from previously reported descriptive and qualitative methods, experts and end-users
47 suggested that the items were potentially difficult for members in our target group (23). The Rasch
48 analyses confirmed this. Furthermore, using the reading items we developed, the respondents reading
49 skills were found to be low. It should be noted that these items have not previously been tested, and
50 served as a pragmatic indicator of the respondents' ability to identify and apply the correct text in
51 response to questions relating to a scenario similar to what we use in the multiple-choice items. We also
52
53
54
55
56
57

1
2
3 explored DIF by reading ability. Only seven out of 88 items displayed evidence of DIF, suggesting that
4 most items work in the same way independent of people's reading ability as measured in this study.
5
6

7 This suggests that efforts should be made to simplify the text in the scenarios and editing the response
8 options to improve readability and improve validity. Reducing the number of response options in the
9 items could also contribute to making the items less difficult.
10
11

12
13 Based on the findings from our analyses, we decided to remove items with non-uniform DIF from the
14 Claim Evaluation Database. We also decided to revise items with poor model fit and reduce response
15 options that did not work as expected. Revised items will be retested in the Ugandan context, where
16 they will be used as an outcome measure.
17
18
19

20
21 A limitation of this study is that we tested the items in only two settings, Uganda and Norway, and that
22 the fit to the Rasch model in other settings is unknown. Further testing of items from the Claim
23 Evaluation Tools database using Rasch Analysis in other countries and languages is needed. We also did
24 not include the respondents' gender in the analysis, which could introduce further DIF. This will be
25 explored in further testing.
26
27
28
29

30
31 There has been an encouraging interest in the Claim Evaluation Tools database in settings other than the
32 countries included in the IHC project, and researchers in Norway, Mexico, Germany and China are
33 currently translating and testing the multiple-choice items in their settings. In addition, the items
34 addressing the Key Concepts we judged to be more advanced, and which were not tested as part of this
35 study, are currently being tested online through www.testingtreatments.org, targeting people with
36 relevant training, such as health researchers or teachers of evidence-based medicine. We are also
37 developing items to assess intended behaviours and attitudes towards assessing treatment claims. The
38 Claim Evaluation Tools database, which includes all of these questions, as well as findings from
39 evaluations such as this one, is freely available for non-commercial use on request through the Testing
40 Treatments interactive website (www.testingtreatments.org).
41
42
43
44
45
46
47
48

49
50 When used for evaluating peoples' ability to assess treatment claims, an item set generated from the
51 Claim Evaluation Tools database can be scored by calculating the number or percentage of correct
52 responses. However, such scores can be difficult to interpret, especially when comparing the average
53 score of two groups (e.g. in a randomised trial). An absolute (criterion referenced) standard for a passing
54
55
56
57

1
2
3 score (i.e. a cut-off for passing) or for mastery of the Key Concepts that are tested. Setting a cut-off
4 requires judgement, and there are several ways of doing this (43-45). For the items that will be used in
5 the trials of the IHC primary school resources and podcast, we have established criteria referenced
6 standards using a combination of Nedelsky's and Angoff's methods (43-46).
7
8
9

10 11 12 **Conclusion**

13
14 We found that most items that we tested had satisfactory fit to the Rasch model. Taken together with
15 our previously reported findings, the findings of this study suggest that the items have face and
16 construct validity in the settings in which they have been tested. Following revisions of some items,
17 informed by the findings from this study, most of the items that we tested are suitable for use in an
18 outcome measure that evaluates people's ability to apply the key concepts they need to know to be able
19 to assess treatment claims.

28 **Authors' contributions**

29
30 AA, ØG, AO wrote the protocol and the IHC group provided comments to this protocol. The Claim
31 Evaluation Tools database was developed by the IHC group. AA coordinated all of the development and
32 evaluation process with support from AO. DS, AN and KO performed the data collection and data entry
33 from the field-testing. ØG and AA prepared the data files for the analysis, and conducted the Rasch
34 analyses. AA authored this manuscript with significant input from the IHC group.

21. A review summarized studies comparing playing sports with other ways of making people happy. The review authors included all studies that found that sports improve people's happiness. Based on these studies, the review authors said that sport definitely improves happiness.

Question: **Do you agree with what the review authors said?**

Options:

- A) It is not possible to say without knowing the opinion of sports experts
- B) No. The review authors included only those studies with favorable results
- C) Yes. The review authors were sure that sports improves happiness
- D) Yes, the review authors included all of the studies with favorable results

Answer:

1. A doctor did a study to find out if drinking tea keeps people from getting sick. The doctor tossed a coin to decide who should get the tea and who should not. People who got tea went to the doctor's office every day to drink their tea. At the end of the study, people who got the tea were less likely to be sick than those who got no tea.

Based on the text above, please answer the following questions:

1.1 Who went to the doctor's office every day?

Options:

- A) People who did not get tea
- B) People who got tea
- C) Everyone
- D) People who got sick

Answer:

1.2. How did the doctor decide who should get tea?

Options:

- A) By tossing a coin
- B) By asking people what they would like
- C) They gave tea to those who were more likely to be sick
- D) They asked people who came to their office

Answer:

1.3. What was the treatment?

Options:

- A) Tea
- B) Sleep
- C) The study
- D) The doctors

Answer:

1.4. What was the result of the study?

Options:

- A) Drinking tea can help people from getting sick
- B) Doctors should toss coins when doing studies
- C) People should go to the doctor if they are sick
- D) Not drinking tea can help people from getting sick

Answer:
