Response to Reviewers:	<p>Reviewer reports: Reviewer #1: Re-review on manuscript BS-virus-finder: virus integration calling using bisulfite-sequencing data Shengjie Gao, Ph.D; Xuesong Hu; Changduo Gao; Kai Xiong; Fengping Xu; Xiao Zhao; Haixiao Chen; Shancen Zhao; Mengyao Wang; Dongke Fu; Xiaohui Zhao; Jie Bai; Bo Li; Song Wu; Shengbin Li; Huanming Yang; Lars Bolund; Christian Pedersen. by Lada A Koneva, PhD</p> <p>Introduction The reviewed manuscript (BS-virus-finder: virus integration calling using bisulfite-sequencing data) describes developed software to detect viral integration breakpoints in whole-genome bisulfite-sequencing data (WGBS). The manuscript was improved according to my suggested concerns and questions, but there are still some questions.</p> <p>Questions As a consequence of choosing HBV for simulation and PLC/PRF/5 hepatocellular carcinoma cell lines (which harboring HBV) as a real data, there is still unanswered my question about how this algorithm will work in case of HPV integration. There are about 170 types of HPV, with high commonality between different types, and about 15 types are carcinogenic. How authors suggest creating a "hybrid reference that contains both human genome and virus sequences" in case of HPV? Which viral types could be chosen for alignment of assembled clipping regions in case of HPV contamination? Probably this algorithm could not accurately predict which type(s) of HPV contaminates the sample. It would be useful if authors could provide their thoughts if this algorithm also will work in case of virus like HPV or this should be restricted to analysis of HBV integration only.</p> <p>Although most programs input only one virus sequence, BSVF users are allowed to set their own multiple virus sequences. For each custom virus genome, BSVF constructs a hybrid reference by combining the virus sequences and human reference. For viruses with large number of strains, such as HPV, to get more meaningful results, we suggest users select some representative sequences from highly similar (such as >90% similarity) sequences.</p> <p>How many reads were simulated in each simulation scenario? Did the authors vary the sequencing depth in the simulations?</p> <p>We simulated all possible reads base by base with selected insert size in each scenario, and the number of reads in each scenario are not equal. The varied depth and the number of reads were listed for each scenario in updated Supplementary Table 6.</p> <p>Minor 1. Section "Description in silico and real data": authors mentioned that simulated reads were selected from chr 18 of GRCh38 and then next sentence "Input fragments were selected from chr 18 in the GRCh37 assembly (hg19) of the human genome". Please, correct this if it's your typo, or clarify why different versions of reference genome were used for simulation. All data used in the manuscript were based on simulation of chr1, although we have also simulated chr18. Thanks. We have revised the text.</p> <p>2. Also they are still using the word "stimulated" instead of "simulated". And in the section "Availability of supporting data" the chromosome 1 was mentioned as chosen</p>

	<p>for simulation. Please correct it. Also typo on page 14-15: "We stimulated three kinds of reads, PE50, 90, and 50" should be 150.</p> <p>As the answer to the above question, all descriptions in the manuscript were revised to chr1. Thank you, we have also revised the typo.</p> <p>3. Legend to Figure 1: The sentence "Methylation sites were showed as read bases" do you mean "red" bases? Thank you for your comments, we revised the typo.</p> <p>4. The information for which virus was used for the simulation of the viral integration is mentioned only at the end of the manuscript (Availability of supporting data). Please provide this information in section "Description in silico and real data". Thank you for your comments, we revised the text based on your suggestion.</p>
Additional Information:	
Question	Response
Are you submitting this manuscript to a special series or article collection?	No
<p>Experimental design and statistics</p> <p>Full details of the experimental design and statistical methods used should be given in the Methods section, as detailed in our Minimum Standards Reporting Checklist. Information essential to interpreting the data presented should be made available in the figure legends.</p> <p>Have you included all the information requested in your manuscript?</p>	Yes
<p>Resources</p> <p>A description of all resources used, including antibodies, cell lines, animals and software tools, with enough information to allow them to be uniquely identified, should be included in the Methods section. Authors are strongly encouraged to cite Research Resource Identifiers (RRIDs) for antibodies, model organisms and tools, where possible.</p> <p>Have you included the information requested as detailed in our Minimum Standards Reporting Checklist?</p>	Yes
<p>Availability of data and materials</p> <p>All datasets and code on which the conclusions of the paper rely must be either included in your submission or deposited in publicly available repositories (where available and ethically appropriate), referencing such data using</p>	Yes

a unique identifier in the references and in the "Availability of Data and Materials" section of your manuscript.

Have you have met the above requirement as detailed in our [Minimum Standards Reporting Checklist?](#)

BS-virus-finder: virus integration calling using bisulfite-sequencing data

2 **Abstract**

3 **Background:** DNA methylation plays a key role in regulation of gene expression and
4 carcinogenesis. Bisulfite sequencing studies mainly focus on calling SNP, DMR, and ASM.
5 Until now, only a few software tools focus on virus integration using bisulfite sequencing
6 data.

7 **Findings:** We have developed a new and easy-to-use software tool, named as
8 BS-virus-finder (BSVF, RRID: SCR_015727), to detect viral integration breakpoints in whole
9 human genomes. The tool is hosted at <https://github.com/BGI-SZ/BSVF>.

10 **Conclusions:** BS-virus-finder demonstrates high sensitivity and specificity, and it is useful
11 in epigenetic studies and to reveal the relationship between viral integration and DNA
12 methylation. BS-virus-finder is the first software tool to detect virus by using bisulfite
13 sequencing data.

14 **Keyword:** Virus integration, Bisulfite sequencing, Carcinogenesis

1

2 **Findings**

3 **Introduction**

4 DNA methylation plays crucial roles in many areas including development [1, 2] and X
5 chromosome inactivation [3] by regulating genetic imprinting and epigenetic modification
6 without altering DNA sequences. Previous studies have showed strong association of DNA
7 methylation with cancer. The methylation status altering related carcinogenesis [4], cancer
8 recurrence [5] and metastasis [6] has already been revealed by emerging bisulfite sequencing
9 (BS) technology. BS technology can investigate DNA methylation changes with single-base
10 accuracy. Treatment of DNA with bisulfite converts unmethylated cytosine residues to uracil,
11 but leaves 5-methylcytosine residues unmodified [7]. Thus, bisulfite treatment introduces
12 specific changes in the DNA sequence that depend on the methylation status of individual
13 cytosine residues, yielding single-nucleotide resolution information about the methylation
14 status of a segment of DNA (Figure 1). Various analyses can be performed on the altered
15 sequences to retrieve this information. BS technology can reveal differences between
16 cytosines and thymidine and sequence change resulting from bisulfite conversion. For the
17 bases without methylation, all C will change to T on both strands. After directional library
18 preparation, we have two different conversions: The Watson, and the Crick strand, as shown
19 in Figure 1. On the Watson strand, methylated C remains C, and unmethylated C changes to T.
20 On the Crick strand, the reverse complement happens, i.e. methylated C remains C but in
21 sequenced reads it is reverse complemented to G, and unmethylated C changes to T, leading to

1 the reverse complement base A in sequenced reads. Since base C can either be methylated or
2 unmethylated, we can use IUPAC nucleotide code “Y” and “R” to represent C/T and G/A
3 respectively. So, after bisulfite treatment, base C changes to Y on the Watson strand, and base
4 G changes to R on the Crick strand.

5
6 Whole-genome based bisulfite sequencing (WGBS) has been developed to detect DNA
7 methylation. Recent clinical studies showed that DNA methylation is associated with viral
8 integration [8, 9]. Whole-genome BS (WGBS) data can be analyzed to investigate the
9 sequence mapping and alignment via BSMAP [10], Bismark [11] and bwa-meth [12], to detect
10 DMR (different methylation regions) via software QDMR [13], DMAP [14] and SMAP [15],
11 to identify SNP (single nucleotide polymorphism) via software BS-SNPer [16] and Bis-SNP
12 [17], to find ASM (allele-specific DNA methylation) via SMAP [15], Methy-Pipe [18].
13 However, none of them can be used for virus integration loci calling, and no software tool is
14 currently available to detect virus integration loci by analyzing BS data. Therefore, we have
15 developed a software tool to detect the virus integration loci by genome-wide BS analysis.

16 **Description in silico and real data.**

17 Different types of PE (paired-end) reads (50bp, 90bp, 150bp) that include 700 breakpoints in
18 chromosome 1 (chr 1) of GRCh38 were simulated in our study. Input fragments of 50 to 400
19 bp were randomly selected from chr 1 in the GRCh38 assembly of the human genome. HBV
20 genome (GenBank: X04615.1) was used in our simulation. Its integration length was between
21 45 bp and 180 bp. We cut HBV containing segments with given pair-end insert size at all

1 possible positions on every integration events. After alignment, mapping accuracy of each of
2 the 17 different types of reads mapping was calculated (Figure 2). Mapping accuracy varied
3 among the 17 types of read mappings in our simulation (Figure S1, S2, S3). In summary, the
4 accuracies of several kinds of the reads mappings were low (Table S1, S2, S3), which may
5 raise false-negative rate. Generally, however, bwa-meth [12] performed very well.

6
7 Bisulfite sequencing is a marvelous and sophisticated technique to study DNA cytosine
8 methylation. Bisulfite treatment followed by PCR amplification specifically converts
9 unmethylated cytosine to thymine. By cooperating with next generation sequencing
10 technology, it is able to detect the methylation status of every cytosine in the whole genome.
11 Moreover, longer reads make it possible to achieve higher accuracy. Besides simulated data,
12 the PLC/PRF/5 hepatocellular carcinoma cell lines were from American Type Culture
13 Collection (ATCC, Manassas, VA) were cultured as previously described [19]. The cell line
14 was validated by STR makers (Figure S4). We performed WGS and WGBS sequencing of this
15 cell line, the result is showed in Table S4. Table 1 shows the analysis result for WGS data,
16 which was compared with the output results analyzed by Vy-per [20], virus-clip[21] and Virus
17 Finder2 [22].

18 **Methods**

19 *Sample preparation*

20 PLC/PRF/5 hepatocellular carcinoma cell line was obtained from American Type Culture
21 Collection (ATCC, Manassas, VA) and were cultured as previously described [19] , which was

1 also validated by STR makers (Figure S4). Then totally 15 µg DNA was extracted to perform
2 WGS and WGBS sequencing. Sample concentration was detected by fluorometer
3 (QubitFluorometer, Invitrogen). Sample integrity and purification was determined by Agarose
4 Gel Electrophoresis.

5 *Whole genome sequencing*

6 About 1.5 µg gDNA was sonicated to 100-300 bp fragment genome DNA by Sonication
7 (Covaris), purified with QIAquick PCR Purification Kit (Qiagen). Adapter ligation and target
8 insert size fragments recovering, and quantifying library by real-time quantitative PCR
9 (QPCR) (TaqMan Probe) was then performed. The qualified library was sequenced on an
10 Illumina Hiseq X Ten platform and 150bp paired-end reads were obtained. Totally, around 90
11 G clean data were generated.

12 *Whole genome bisulfite sequencing*

13 About 3 µg gDNA were sonicated to 100-300 bp by Sonication (Covaris), purified with
14 MiniElute PCR Purification Kit (QIAGEN). A single 'A' nucleotide was added to the 3' ends
15 of the blunt fragments. Methylated adapters were then purified and added to the 5' and 3' ends
16 of each strand in the genomic fragment. Sizes 300-400bp were selected. DNA was then
17 purified with QIAquick Gel Extraction kit (QIAGEN) and bisulfite treated with
18 Methylation-Gold kit (ZYMO). Finally PCR was conducted and sizes 350-400bp were
19 selected and purified with QIAquick Gel Extraction kit (QIAGEN). Qualified library was
20 amplified on cBot to generate the cluster on the flowcells (TruSeq PE Cluster Kit

1 V3-cBot-HS, Illumina). The flowcells were sequenced for 150 bp pair end reads on HiSeq X
2
3
4 Ten platform and more than 90G clean data were generated.

5 6 7 3 *Data analysis*

8
9
10 4 The reads coverage situation for one integration is shown in Figure 3. Four steps were
11
12
13 5 implemented to detect virus integration:

14 15 16 6 1. Alignment

17
18
19 7 We use bwa-meth [12] to align bisulfite treated sequencing reads to a hybrid reference that
20
21
22 8 contains both human genome and virus sequences. For chimeric reads from the junction parts,
23
24
25 9 BWA-MEM [23] will align it to one organism and mark the unmapped part as soft clipping,
26
27
28 10 which is in fact from the other organism. This enables us to find breakpoints directly from the
29
30
31 11 alignment.

32 33 34 12 2. Clustering

35
36 13 After alignment, the result was filtered. We select read pairs with one read match by the
37
38
39 14 following criterion: the Phred-scaled mapping quality is bigger than 30 (≥ 30), and at least
40
41
42 15 one soft clipping is longer than 5 bp (≥ 5). The mapped parts of reads, which is marked as
43
44
45 16 “M” by its CIGAR string, cover the human reference genome. For paired reads, we also add
46
47
48 17 the gap between two mapped reads to their covered region, making read 1 and read 2 be
49
50
51 18 continuous covered on human reference. Each continuous region with at least 1 bp overlap are
52
53
54 19 defined as a cluster. All reads involved are selected to form the cluster. The remaining soft
55
56
57 20 clippings are viral junction candidates. Read pairs with one read mapped on virus also indicate
58
59
60 21 potential virus junction between the read pair.
61
62
63
64
65

1 3. Assembling

2 Within one cluster, all soft clipping start sites are collected. The position with the most
3 abundance of start sites is identified as the most likely candidate breakpoint. All clipping
4 sequences in the cluster are extracted and aligned together. A restore algorithm was used to
5 calculate the most possible base in each position based on the aligned bases and its sequencing
6 quality. The algorithm is based on a Bayesian model, where we compute the posteriori
7 probability estimation for A, C, G, T as:

$$\begin{aligned}
 P(T_i | D) &= \frac{P(T_{Wi})P(D | T_{Wi})}{\sum_{x=1}^S P(T_{Wx})P(D | T_{Wx})} \times \frac{P(T_{Ci})P(D | T_{Ci})}{\sum_{x=1}^S P(T_{Cx})P(D | T_{Cx})} \\
 &= C_0 \times P(D | T_{Wi}) \times P(D | T_{Ci}) \\
 C_0 &= \frac{P(T_{Wi})}{\sum_{x=1}^S P(T_{Wx})P(D | T_{Wx})} \times \frac{P(T_{Ci})}{\sum_{x=1}^S P(T_{Cx})P(D | T_{Cx})}
 \end{aligned} \tag{1}$$

8 Here, D is the observation of the NGS reads on given position. P(T_i|D) is the likelihood
9 component, which can be interpreted as the probability of observing D when the true genotype
10 is T_i. D_W be a realization (or observation) of the NGS reads in the Watson strand. D_C be a
11 realization (or observation) of the NGS reads in Crick strand. P(T_{Wi}|D) is the likelihood
12 component, which can be interpreted as the probability of observing D when the true genotype
13 is T_{Wi}. P(T_{Ci}|D) is the likelihood component, which can be interpreted as the probability of
14 observing D when the true genotype is T_{Ci}. At each virus location, prior probability P(T_i) of
15 each genotype T_i was set according to the Table S5. The likelihood P(D|T_i) for the assumed
16 genotype T_i was calculated from the observed allele types in the sequencing reads in formula
17 2. Thus, on the Watson strand it is P(D_W|T_i), on the Crick strand it is P(D_C|T_i). We defined the
18 likelihood of observing allele d_k in a read for a possible haploid genotype T as P(d_k|T), and on
19

1 the Watson strand it is $P(d_{wk}|T)$, and on the Crick strand it is $P(d_{ck}|T)$. So, for a set of n
 2 observed alleles at a locus, $D = \{d_1, d_2, \dots, d_n\}$ on each strand, these probabilities are
 3 computed as shown by formula 3 & 4, where Q stands for the base quality from the fastaq file.

$$P(D_w | T_i) = \prod_{k=1}^m P(d_{wk} | T), P(D_c | T_i) = \prod_{k=1}^n P(d_{ck} | T). \quad (2)$$

$$P(d_{wk} | T) = \begin{cases} 1 - 10^{-\frac{Q}{10}} & (T \in \{A, C, G\}) \\ \frac{1 - 10^{-\frac{Q}{10}}}{2} & (T \in \{T\}) \end{cases}, \quad (3)$$

$$P(d_{ck} | T) = \begin{cases} 1 - 10^{-\frac{Q}{10}} & (T \in \{C, G, T\}) \\ \frac{1 - 10^{-\frac{Q}{10}}}{2} & (T \in \{A\}) \end{cases}. \quad (4)$$

6 We used “Y” and “R” to represent C/T and G/A respectively (IUPAC nucleotide code). If a
 7 region is covered by both the Watson strand and the Crick strand, we were able to deduce the
 8 original base from Y or R by calculation.

9 4. Detection of viral integrations

10 The assembled clipping regions above were mapped to the given virus reference sequence
 11 with a Smith-Waterman local alignment tool from EMBOSS package [24], which support
 12 IUPAC DNA codes Y and R. Virus fragment location is extracted from the alignment results.

13 Discussion

14 In summary, we have implemented the first software tool to detect virus integration using BS
 15 data. Our software is based on bwa-meth, and by assembling and aligning soft-clip regions, it
 16 can find the virus breakpoints. However, accuracy of reads surrounding the breakpoints needs
 17 to be further improved. Virus usually integrates into regions that are homologous to both
 18 human and virus (micro-homologous) [25]. Therefore, we consider the breakpoints predicted
 19 by our software tool that are within 10 bp of a real breakpoint as being correctly identified

(Figure S2). With this definition, the accuracy of our predicted breakpoints can reach over 70%. Our results will be useful for analyzing BS data and related applications. Some of the results come with only location on human genome, and has the virus location missing. This may be due to the shortage of virus fragments. We simulated three kinds of reads, PE50, 90, and 150 with various lengths, and further simulated virus-inserted fragment with different length as well (Table S6), thus all cases described in Figure 2 are mimicked here. All simulation sampled all possible reads, base by base with fixed insert size. As the result in Table S6 showed, the longer the reads, the more accurate the prediction can be achieved. In particular, for read lengths around 50 bp, BS-virus-finder is capable to find the virus integration with an accuracy of more than 70%; for the read lengths between 90bp and 150bp, BS-virus-finder is capable to find the virus integration with an accuracy of more than 90%. Besides simulated data, we have performed WGS and WGBS sequencing of the PLC/PRF/5 hepatocellular carcinoma cell line (Table S4). As the results showed, when the length of input is larger than 150bp, the analysis result of WGBS is similar to the one of WGS. Additionally, BS-virus-finder is able to find breakpoints in 8 out of 9 regions which are identified by FISH [8]. Based on these experimental results, we believe that BS-virus-finder is a powerful software tool to analyze virus-integration using BS data.

Availability and requirements

Project Name: BS-virus-finder: virus integration calling using bisulfite-sequencing data

Project home page: <https://github.com/BGI-SZ/BSVF> [26]

Operating system: Linux

1 Programming language: Perl, Python, C

2 License: LGPL v3

3

4 **Availability of supporting data**

5 Data used in this paper is simulated based on random insertion of HBV sequence to human
6 chromosome 1 sequence. A Perl script named “simVirusInserts.pl” is included, and our
7 simulation schema is coded within. We have run the simulation several times and the result
8 shows no significant difference. The PLC/PRF/5 hepatocellular carcinoma cell lines were
9 from American Type Culture Collection (ATCC, Manassas, VA) and sequenced by HiSeq X
10 Ten System from Novogene company. WGS and WGBA data have been submitted to NCBI
11 SRA project PRJNA400455.

12

13 **Competing interests**

14 The authors declare that they have no competing interests.

15

16 **Authors' contributions**

17 CP, LB and HY conceptualized the project. SG, XH, SL and JW designed BSVF and
18 developed its accompanying utilities. SG, XH, CG, XZ, MW and SZ developed the protocol.
19 FX, DF, HC and JB conducted experiment. SG, XH, BL and SW undertook the analysis. KX,
20 LM, SG, XH, LB and CP wrote and approved the final version of the manuscript. All authors
21 read and approved the final manuscript.

BSVF used WGBS data, and other software used WGS data.

* supported by previous FISH experiments [8].

HB: Host breakpoint.

VB: Virus Begin is the revealed left most position on virus.

VE: Virus End is the right most position on virus.

1

2 **Figure 1. The illustration of bisulfite-altered sequence to the original.**3 Reference is the original sequence prior to bisulfite treatment. After directional library preparation, we
4 have two different conversion: Watson and Crick strand.5 Methylation sites were showed as red bases. Bisulfite treated base may alter the original base from C to
6 T. m indicated methylation-modified base. Low-case letter indicates the bisulfite-altered base.7 As we can see, half of the probability of each T is C in Watson strand and half of the probability of each
8 A is G in Crick strand.

Figure 3. A demo plot of one viral integration cluster in its pre-insertion form.

Plot was randomly selected from simulated breakpoints.

The red virus fragment(V) above will be inserted into the center point of the green(L) and blue(R) human fragment below to form the sequenced sample. Bars show the coverage depth of sequencing reads.

Curves represent the linkage events supported by pair-end sequencing reads, and the number besides shows the read count.

Submission of final version of paper

Dear Editor in Chief

Thank you very much for accepting our paper "BS-virus-finder: virus integration calling using bisulfite-sequencing data" (GIGA-D-17-00032R1) cf. your e-mail dated September 29, 2017. We have addressed the points raised by the reviewers to the best of our abilities, and as outlined in our response to reviewers. We hope that you find everything in order.

Kind regards

Christian Nørgaard Storm Pedersen
(on behalf of all the authors of the paper)
