

Supplementary Figure 1 | Subsequent memory effect (SME) at stimulated electrode pair. (a,b) The subsequent memory effect during the record-only sessions at the stimulated electrode pair did not differ between the Lateral temporal and Non-lateral temporal groups (two-sample t-tests). Stimulated electrodes demonstrated a spectral tilt in the SME: positive SMEs at high frequencies (> 40 Hz) and negative SMEs at low frequencies (3–8 Hz). (c) We computed the slope of the frequency spectrum to measure the spectral tilt at the stimulated electrode pair and found this measure did not correlate with the effect of stimulation on memory performance in later closed-loop sessions (Pearson correlation). Data are presented as mean \pm s.e.m.

Supplementary Figure 2 | Evoked high-frequency power following stimulation. Within electrodes that were placed in the same lobe and hemisphere as the stimulation target, we extracted wavelet power for 1000~ms windows following stimulation and matched NoStim epochs. We averaged power over time and computed unpaired t-tests within each electrode and wavelet frequency in the high-frequency range (70--200~Hz). We then averaged these t-statistics across electrodes and across subjects to derive an aggregated estimate of the effect of stimulation on high-frequency power near the stimulation target site. Across subjects, high-frequency power was not reliably modulated by stimulation in the same lobe as the stimulation target ($P_{LatTemp} = 0.40$; $P_{NonLatTemp} = 0.99$; $P_{LatTemp-NonLatTemp} = 0.61$, $N_{LatTemp} = 18$, $N_{NonLatTemp} = 11$). Data are presented as mean \pm s.e.m.

Supplementary Table 1 | Patient Information

Subject	Site	Gender	Age	Ictal Onset	Task	Stimulation Parameters					Stim Prec	NoStim Prec
