General Information

Tetrahydrofuran (THF), *N*,*N*-dimethylformamide (DMF), acetonitrile (CH_3CN) and dichloromethane (CH_2Cl_2) were obtained by passing the previously degassed solvents through activated alumina columns. Purity and source of reagents were listed on Page S19. Reagents were used as received without further purification, unless otherwise stated. Yields refer to chromatographically and spectroscopically (^1H NMR) homogeneous material, unless otherwise stated. Reactions were monitored by GC/MS, LC/MS, and thin layer chromatography (TLC). TLC was performed using 0.25 mm E. Merck silica plates (60F-254), using short-wave UV light as visualizing agent, as well as potassium permanganate ($KMnO_4$) or ceric ammonium molybdate (CAM) and heat as developing agents. NMR spectra were recorded on Bruker DRX-600, DRX-500, or DPX-400 instruments and were calibrated using residual undeuterated solvent (^1H: δ 7.26 for $CDCl_3$, δ 3.31 for MeOH-d_4, δ 3.58, 1.73 for THF-d_8, δ 2.50 for DMSO-d_6, δ 2.05 for acetone-d_6; ^{13}C: δ 77.16 for $CDCl_3$, δ 49.0 for MeOH-d_4, δ 67.6, 25.5 for THF-d_8, δ 39.50 for DMSO-d_6, δ 29.84 for acetone-d_6). The following abbreviations were used to explain multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br = broad. Column chromatography was performed using E. Merck silica gel (60, particle size 0.043-0.063 mm), and preparative TLC was performed on 0.25 mm E. Merck silica plates (60F-254). High resolution mass spectra (HRMS) were recorded on an Agilent LC/MSD TOF mass spectrometer by electrospray ionization time of flight reflectron experiments. Preparative high performance liquid chromatography (HPLC) was performed using an Agilent SD-1 prepstar system equipped with Phenomenex Gemini 10 μm C18 column with dimension 200 × 50 mm. Melting points were recorded on a Fisher-Johns 12-144 melting point apparatus and are uncorrected. All X-ray diffraction data were collected and analyzed by the UCSD small molecule X-ray facility. The deactivated silica gel (35 wt% H_2O) was prepared by mixing silica gel and deionized water, followed by vigorous shaking until a fluffy powder was observed.

General Procedure for the Synthesis of Redox-active Esters (RAEs) (General Procedure A)

A round bottom flask was charged with carboxylic acid (1.0 equiv.), *N*-hydroxyphthalimide (NHPI, 1.0 equiv.) or tetrachloro-*N*-hydroxyphthalimide (TCNHPI, 1.0 equiv.), and DMAP (0.1 equiv.). CH_2Cl_2 (0.2 M) was added, followed by *N*,*N'*-diisopropylcarbodiimide (DIC, 1.1 equiv.), both at room temperature (RT). The mixture was allowed to stir until all the acid was consumed (as indicated by TLC). The resulting mixture was quickly filtered and the solid residue was rinsed with more CH_2Cl_2. The filtrate was concentrated *in vacuo* and purified by flash column chromatography to afford the corresponding redox-active ester (RAE), which was used without further purification unless otherwise noted.

Note: Some RAEs that are prone to hydrolysis on silica gel during column chromatography were purified by recrystallization or column chromatography using deactivated silica gel (35 wt% H_2O).

General Procedure for Nickel Catalyzed Decarboxylative Borylation

Part I. Preparation of $NiCl_2$•$6H_2O$/Ligand Stock Solution or Suspension

(1) Suspension A: $NiCl_2$•$6H_2O$/di-MeObipy (**L1**) in THF (0.025 M).

A screw-capped culture tube charged with $NiCl_2$•$6H_2O$ (23.8 mg, 0.1 mmol) and 4,4′-dimethoxy-2,2′-bipyridine (**L1**, 28.1 mg, 0.13 mmol) was evacuated and backfilled with argon for three times. THF (4.0 mL) was added and the resulting mixture was stirred at room temperature overnight (or until no granular $NiCl_2$•$6H_2O$ was observed) to afford a pale green suspension.

(2) Suspension B: $NiCl_2$•$6H_2O$/di-MeObipy (**L1**) in DMF (0.05 M).

A screw-capped culture tube charged with $NiCl_2$•$6H_2O$ (23.8 mg, 0.1 mmol) and 4,4′-dimethoxy-2,2′-bipyridine (**L1**, 28.1 mg, 0.13 mmol) was evacuated and backfilled with argon for three times. DMF (2.0 mL) was added and the resulting mixture was stirred at room temperature overnight to afford a pale green suspension.

(3) Suspension C: $NiCl_2$•$6H_2O$/di-*t*Bubipy (**L2**) in THF (0.025 M).

A screw-capped culture tube charged with $NiCl_2$•$6H_2O$ (23.8 mg, 0.1 mmol) and 4,4′-di-*tert*-butyl-2,2′-bipyridine (**L2**, 34.8 mg, 0.13 mmol) was evacuated and backfilled with argon for three times. THF (4.0 mL) was added and the resulting mixture was stirred at room temperature overnight (or until no granular $NiCl_2$•$6H_2O$ was observed) to afford a pale green suspension.

(4) Solution D: $NiCl_2$•$6H_2O$/di-*t*Bubipy (**L2**) in DMF (0.05 M).

A screw-capped culture tube charged with $NiCl_2$•$6H_2O$ (23.8 mg, 0.1 mmol) and 4,4′-di-*tert*-butyl-2,2′-bipyridine (**L2**, 34.8 mg, 0.13 mmol) was evacuated and backfilled with argon for three times. DMF (2.0 mL) was added and the resulting mixture was stirred at room temperature for 2 h to afford a green solution.

Note: All the solutions or suspensions kept under argon can be used for two weeks without appreciable deterioration in reaction yields.

Part II. Preparation of [B_2pin_2Me]Li Complex

To a solution of B_2pin_2 (168 mg, 0.66 mmol) in THF (0.6 mL) was added MeLi (0.38 mL, 1.6 M in Et_2O, 0.6 mmol) at 0 °C under argon. The reaction mixture was warmed to room temperature and stirred for 1 h to afford a suspension (sometimes a clear solution was observed).

Note: The resulting mixture can be stored under constant stirring for 12 hours without appreciable deterioration.

Part III. Nickel Catalyzed Decarboxylative Borylation

General Procedure B

A screw-capped culture tube charged with redox-active ester (0.2 mmol, 1.0 equiv.) and $MgBr_2$•OEt_2 (77 mg, 0.3 mmol, 1.5 equiv.) was evacuated and backfilled with argon for three times. THF (0.8 mL) was added, and the mixture was stirred until no granular $MgBr_2$•OEt_2 was observed (*ca.* 10 min, sonication could promote this process) before suspension B [0.4 mL, $NiCl_2$•$6H_2O$ (10 mol%)/di-MeObipy (13 mol%) in DMF], or solution D [0.4 mL, $NiCl_2$•$6H_2O$ (10 mol%)/di-*t*Bubipy (13 mol%) in DMF] was added via a syringe. The resulting mixture was stirred vigorously until no visible solid was observed on the bottom of the reaction vessel (*ca.* 10 min, sonication could promote this process). This mixture was cooled to 0 °C before a suspension of [B_2pin_2Me]Li in THF (3.0 equiv., 1.1 mL) was added in one portion (*note: do not add it dropwise!*). After stirring for 1 h at 0 °C, the reaction was warmed to room temperature and stirred for another 1 h before quenching with 0.1 N HCl (10 mL). The resulting mixture was extracted with Et_2O or EtOAc (3 mL×2). The combined organic layers were concentrated *in vacuo*, and the crude product was purified by flash column chromatography. For acid labile substrates, the reaction was alternatively quenched with saturated aqueous NH_4Cl (10 mL).

General Procedure C

A screw-capped culture tube charged with redox-active ester (0.2 mmol, 1.0 equiv.) and $MgBr_2$•OEt_2 (77 mg, 0.3 mmol, 1.5 equiv.) was evacuated and backfilled with argon for three times. Suspension A [0.8 mL, $NiCl_2$•$6H_2O$ (10 mol%)/di-MeObipy (13 mol%) in THF] or C **[**(0.8 mL, $NiCl_2$•$6H_2O$ (10 mol%)/di-*t*Bubipy (13 mol%) in THF] was added via a syringe. The mixture was stirred vigorously at room temperature until no granular $MgBr_2$•OEt_2 was observed (*ca.*10 min, sonication could promote this process). This suspension was cooled to 0 °C before a suspension of [B_2pin_2Me]Li was added in one portion (*note: do not add it dropwise!*). After stirring for 1 h at 0 °C, the reaction was warmed to room temperature and stirred for another 1 h. The reaction mixture was diluted with Et_2O (10 mL), filtered through a short pad of silica gel and celite (top layer: celite, bottom layer: silica gel, v/v celite:silica gel = 1:1), and washed with Et_2O (50 mL). The filtrate was concentrated, and the crude product was purified by flash column chromatography.

For polar substrates, such as peptides, the reaction was quenched either with 0.1 N HCl (10 mL) or saturated aqueous NH_4Cl (10 mL) followed by extraction with EtOAc (3 mL×2). The combined organic layers were dried over anhydrous Na_2SO_4, concentrated *in vacuo* and purified by flash column chromatography.

Note:

1. *Addition of THF to solid $MgBr_2$•OEt_2 is* ***exothermic****.*
2. *Addition of [B_2pin_2Me]Li to the reactiom mixture is* ***exothermic****.*

General Procedure for Gram Scale Nickel Catalyzed Decarboxylative Borylation (Ibuprofen)

The gram scale procedure was adapted from **General Procedure C**. A flame-dried round bottom fask charged with B_2pin_2 (2.57 g, 10.1 mmol, 3.3 equiv.) was evacuated and backfilled with argon for three times. THF (9.2 mL) was added, and the clear solution was cooled to 0 °C when MeLi (5.8 mL, 1.6 M in Et_2O, 9.3 mmol, 3.0 equiv.) was added dropwise. The reaction mixture was then warmed to room temperature and stirred for 1 h.

The NHPI redox-active ester of ibuprofen **S16** (1.08 g, 3.07 mmol, 1.0 equiv.) and $MgBr_2$•OEt_2 (792 mg, 3.07 mmol, 1.0 equiv.) were sequentially added to another flame-dried round-bottom flask. This flask was evacuated and backfilled with argon for three times and was cooled to 0 °C. THF (12 mL) was added, followed by a suspension of $NiCl_2$•$6H_2O$ (73 mg, 0.31 mmol, 10 mol%) and di-MeObipy (**L1**, 86 mg, 0.40 mmol, 13 mol%) in THF (12 mL), The resulting mixture was sonicated until there was no visible solid on the bottom of the flask. The mixture was then cooled to 0 °C before a suspension of $[B_2pin_2Me]Li$ in THF was added in one portion. After stirring for 1 h at 0 °C, the reaction mixture was warmed to room temperature and stirred for another 1 h.

The reaction mixture was then poured into Et_2O (100 mL), and the flask was rinsed with additional Et_2O (100 mL). The resulting mixture was filtered through a plug of silica gel and celite (top layer: celite, bottom layer: silica gel, v/v celite:silica gel = 1:1), the solid residue was washed with Et_2O (350 mL), and the filtrate was concentrated *in vacuo*. Purification by flash column chromatography (silica gel, hexanes to 1:30 Et_2O: hexanes) furnished the product (709 mg, 80%) as a colorless oil.

Note:

*1, Addition of THF to solid $MgBr_2$•OEt_2 is **exothermic**.*

*2, Addition of $[B_2pin_2Me]Li$ to the reactiom mixture is **exothermic**.*

A screw-capped culture tube equipped with a stir bar was charged with alkyl carboxylic acid (0.2 mmol, 1.0 equiv.), *N*-hydroxyphthalimide or tetrachloro-*N*-hydroxyphthalimide (0.2 mmol, 1.0 equiv.) and *N,N'*-dicyclohexylcarbodiimide (0.2 mmol, 1.0 equiv.). The tube was then evacuated and backfilled with argon for three times. CH_2Cl_2 (2.0 mL) was added and the resulting mixture was stirred at room temperature for 2 h before the volatiles were removed *in vacuo*. $MgBr_2$•OEt_2 (77 mg, 0.3 mmol, 1.5 equiv.) was added. The tube was evacuated and backfilled with argon for three times. Suspension A [0.8 mL, $NiCl_2$•$6H_2O$ (10 mol%)/**L1** (13 mol%) in THF] or suspension C [0.8 mL, $NiCl_2$•$6H_2O$ (10 mol%)/**L2** (13 mol%) in THF] was added. The mixture was stirred vigorously at room temperature for 10 min (or until no granular $MgBr_2$•OEt_2 was observed) and was subsequently cooled to 0 °C before a suspension of [B_2pin_2Me]Li in THF (1.1 mL) was added in one portion (*note: do not add it dropwise!*). After stirring at that temperature for 1 h, the reaction was warmed to room temperature and stirred for another 1 h. The reaction mixture was then quenched with 0.1 N HCl (10 mL) and extracted with Et_2O (5 mL×2). The combined organic layers were dried over anhydrous Na_2SO_4, concentrated *in vacuo* and purified by column chromatography to afford the desired product.

A screw-capped culture tube charged with $NiCl_2$•$6H_2O$ (23.8 mg, 0.1 mmol) and 4,4′-dimethoxy-2,2′-bipyridine (**L1**, 28.1 mg, 0.13 mmol) was evacuated and backfilled with argon for three times. THF (16.0 mL) was added and the resulting mixture was stirred at room temperature overnight (or until no granular $NiCl_2$•$6H_2O$ was observed) to afford a pale green suspension.

(2) Solution F: $NiCl_2$•$6H_2O$/di-MeObipy (**L1**) in DMF (12.5 mM).

A screw-capped culture tube charged with $NiCl_2$•$6H_2O$ (23.8 mg, 0.1 mmol) and 4,4′-dimethoxy-2,2′-bipyridine (**L1**, 28.1 mg, 0.13 mmol) was evacuated and backfilled with argon for three times. DMF (8.0 mL) was added and the resulting mixture was stirred at room temperature overnight to afford a light green solution.

Troubleshooting and Frequently Asked Questions (FAQs):

Part I. Redox-active Ester Synthesis

Question 1:

Some polar redox-active esters (RAEs), such as those derived from amino acids or peptides, are very prone to hydrolysis on silica gel. How can I isolate them?

Answer:

Purification by flash column chromatography using deactivated silica gel (35 wt% H_2O) is recommended.

Question 2:

How does the retention factor of the products change when using deactivated silica gel (35 wt. % H_2O)?

Answer:

The adsorption capacity of deactivated silica gel (35 wt% H_2O) is lower than the normal silica gel. Thus, a less polar eluent should be used compared to normal.

Part II. Preparation of $NiCl_2$•$6H_2O$/Ligand Stock Solution or Suspension

Question 1:

$NiCl_2$•$6H_2O$ has very low solubility in THF in the presence of di-MeObipyl (**L1**) or di-*t*Bubipyl (**L2**). How do I proceed?

Answer:

The complexes of $NiCl_2$•$6H_2O$/**L1** and $NiCl_2$•$6H_2O$/**L2** do not dissolve well in THF. However, a very good suspension of such complexes can be afforded after vigorous stirring overnight. ***Tips:*** It is much easier to get good suspensions (4 – 6 h), if the culture tube was placed at the edge of a stir plate (with a stirring rate of 500 – 800 rpm) instead of the center (see below).

Question 2:

How can I make sure that I have added the precise amount of $NiCl_2$•$6H_2O$/**L1** or $NiCl_2$•$6H_2O$/**L2** as these complexes do not fully dissolve in THF?

Answer:

The precise amount of catalyst complexes can be drawn out from a "homogeneous" suspension under vigorous stirring.

Question 3:

If there are precipitates in catalyst suspensions A, B, or C, can I still use them?

Answer:

Yes, they can be still used after stirring.

Part III. Preparation of [B_2pin_2Me]Li Complex

Question 1:

Do I have to use 3.0 equiv. of [B_2pin_2Me]Li?

Answer:

2.5 equiv. of [B_2pin_2Me]Li also works fine for most of the subtrates. Addition of more than 3.0 equiv. of [B_2pin_2Me]Li, nevertheless, does not help the borylation reaction.

Question 2:

How can I monitor the [B_2pin_2Me]Li complex formation?

Answer:

It is very hard to monitor the formation of [B_2pin_2Me]Li complex, but we have determined that the reaction between MeLi and B_2pin_2 is completed in 1 h. If the reaction is run for less than 30 min, unreacted MeLi could destroy some base sensitive substrates (such as Fmoc protected amino acids), leading to lower yields.

Question 3:

If I get a clear solution of [B_2pin_2Me]Li instead of a white suspension after stirring for 1 h, what can I do?

Answer:

In a few cases, we have also obtained a clear solution after stirring for 1 h. It was found that both clear solution and white suspension worked fine for the borylation reaction.

Question 4:

How long can I keep the suspension of [B_2pin_2Me]Li in THF?

Answer:

The suspension of [B_2pin_2Me]Li in THF can be kept at room temperature for 12 h under stirring. A lower yield was observed if the suspension was left for more than 12 h. This complex is not very stable under air and should thus be kept under an inert atmosphere.

Part IV. Nickel Catalyzed Decarboxlyative Borylation

Question 1:

If I only have a small amount of carboxylic acid material, which condition would you suggest to try first?

Answer:

A flow chart is provided on page S32 to guide the selection of optimal conditions for

different structural classes of substrates.

Question 2:

Have you tried any other magnesium salts for this reaction?

Answer:

During our initial screening, we examined several magnesium salts, such as $MgCl_2$, $Mg(OAc)_2$, $Mg(acac)_2$, $MgSO_4$, *etc*., among which $MgBr_2$•OEt_2 gave the best yield.

Question 3:

Can I change the amount of $MgBr_2$•OEt_2 to increase the yield?

Answer:

Generally, more than 2.0 equiv. or less than 1.2 equiv. of $MgBr_2$•OEt_2 led to diminished yields. However, for the 2° benzylic RAEs, 1.0 equiv. proved to be sufficient for the borylation reaction.

Question 4:

Can I use granular $MgBr_2$•OEt_2 in this reaction?

Answer:

Granular $MgBr_2$•OEt_2 can be used in this reaction, but longer stirring time (until no granular $MgBr_2$•OEt_2 was observed) was required before the addition of $[B_2pin_2Me]Li$ complex. $MgBr_2$•OEt_2 powder is therefore highly recommended.

Question 5:

If there is granular $MgBr_2$•OEt_2 left after stirring for 15 min, what can I do?

Answer:

Sonicate the mixture or stir for longer periods of time.

Question 6:

Can I add the $[B_2pin_2Me]Li$ complex at room temperature?

Answer:

This borylation reaction is ***exothermic***. The reaction temperature would increase a lot if $[B_2pin_2Me]Li$ complex was added at room temperature, leading to lower yields.

Question 7:

How do you monitor the reaction?

Answer:

We monitor the reaction by TLC (UV visualization or staining based on redox-active esters). Reactions on all substrates examined herein (> 40 examples) were completed in 1 h at 0 °C and another 1 h at room temperature. Longer reaction time generally lead to lower yield. Shorter reaction time is recommended for substrates that are conceivably unstable under the reaction conditions.

Question 8:

How can I detect the pinacol alkylboronate esters (alkyl-Bpin) on TLC?

Answer:

Most of the pinacol alkylboronate esters are sensitive to ceric ammonium molybdate (CAM, Hanessian's stain) and potassium permanganate ($KMnO_4$). You can also detect the product *via* UV visualization if your product is UV active. GC/MS and LC/MS are also recommended.

Question 9:

What other possible byproduct were observed in this reaction?

Answer:

We occasionally observed hydrodecarboxylation, decarboxylative dimerization or the hydrolysis (to carboxylic acids) of RAEs.

Question 10:

Is there any indicative color change during the reaction?

Answer:

The color of the coupling reaction varies for different substrates. Normally, we observed a color change from green to yellow, brown, or black after addition of the $[B_2pin_2Me]Li$ complex.

Question 11:

Can I purify the pinacol alkylboronate esters (alkyl-Bpin) on preparative TLC?

Answer:

The pinacol alkylboronate esters are not very stable on preparative TLC due to possible oxidation of C–B bond or hydrolytic cleavage of pinacol esters. Usually, we purify the products using flash column chromatography with gradient elution. Some pinacol α-aminoboronate esters were purified by flash column chromatography with gradient elution using deactivated silica gel (35 wt% H_2O).

Question 12:

Are the pinacol alkylboronate esters bench-stable?

Answer:

Most of the pinacol alkylboronate esters we made can be stored under air at room temperature for two weeks without appreciable decomposition. Normally, we store them under argon at –20 °C.

Question 13:

If the desired product was contaminated with some phthlimide after column, what can I do to remove it and get the pure product?

Answer:

Most of the pinacol alkylboronate esters can be dissolved in hexanes, but phthlimide

can not. Thus one can dissolve the product in hexanes and filter it through celite to remove the phthlimide.

Question 14:

Although I am able to obtain some product, the yield is not satisfactory for my purposes. How should I optimize the reaction?

Answer:

For further optimization, we recommend the following:

1. Screen the four nickel catalytic systems first (suspension A, B, C and solution D).
2. If NHPI ester does not work well, try TCNHPI redox-active ester.
3. Try a higher loading of nickel precatalyst.
4. If suspension B or solution D work better than suspension A or C, one can also try to use DMA instead of DMF.

Part V Nickel Catalyzed *in situ* Decarboxlyative Borylation of Alkyl Carboxylic Acids

Question 1

Can I use DIC instead of DCC as coupling reagent in this *in situ* coupling reaction?

Answer:

We have tried both of them and found that DCC gave better yield than DIC.

Question 2

When is the *in situ* protocol applicable?

Answer:

The protocol is suitable for secondary and tertiary carboxylic acids. Lower yields were obtained for primary substrates. Also, the quality of DCC was found to be critical.

Part VI. Deprotection of Pinacol Alkylboronate Esters

Question 1

Are the alkyl boronic acids stable?

Answer:

1. Alkyl boronic acids on tertiary carbon are prone to oxidation. We only obtained the corresponding alcohols instead of desired boronic acids after column chromatography or preparative TLC.

2. Alkyl boronic acids on primary and secondary carbon are relatively stable and can survive quick purifications.

3. α-Amino boronic acids containing electron-withdrawing protecting group on amine are relatively stable.

4. Alkyl boronic acids are prone to dimerization and trimerization, but they can generally be stabilized through addition of water.

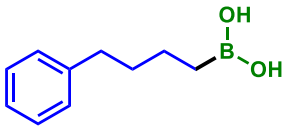
Experimental Procedure and Characterization Data for Boronic Acids

Compound 4a



4a

(4-phenylbutyl)boronic acid (4a)

Pinacol boronate ester **4** (70 mg, 0.27 mmol) was dissolved in CH_2Cl_2 (5 mL) under argon and the solution was cooled to −78 °C in a dry ice/acetone bath. BCl_3 (0.81 mL, 1.0 M in CH_2Cl_2, 3.0 equiv.) was added dropwise, after which the mixture was stirred for 1 h at −78 °C. The mixture was then allowed to warm up to room temperature, and the volatiles were removed *in vacuo*. Anhydrous methanol (5 mL) was added and the resulting mixture was stirred for 10 minutes when methanol was removed *in vacuo*. An additional portion of methanol (5 mL) was added; the mixture was stirred for 10 minutes before it was concentrated *in vacuo*. This process was repeated for another three times. (2,5-dichlorobenzoyl)glycylleucine (S41)

Removal of Boc: To a solution of Boc-Gly-Leu-OMe (*61*) (**S40**, 3.1 g, 10.36 mmol) in CH_2Cl_2 (30 mL) was added TFA (15 mL) at room temperature, the reaction mixture was stirred for 1 h before concentration *in vacuo*. The residue was used directly in the next step.

Amide bond formation: To a solution 2,5-dichlorobenonic acid (2.94 g, 15.4 mmol) in THF (70 mL) was added 4-methylmorpholine (4.0 mL, 35.9 mmol) at –15 °C, the reaction mixture was stirred for 10 min at that temperature. To the resulting white

The crude TFA salt (from the deprotection step) in THF (35 mL) was added slowly at the same temperature. The reaction mixture was warmed up to room temperature and stirred for 6 h. The resulting mixture was diluted with EtOAc (100 mL), washed with water (100 mL), sat. aqueous $NaHCO_3$ (100 mL), and brine (100 mL). The combined organic layer was dried over anhydrous Na_2SO_4, filtered, and concentrated. Purification by flash column chromatography (silica, 3:2 Hexane/EtOAc) afforded the desired ester which was directly used in next step without further purification.

Hydrolysis of methyl ester: To a solution of the aforementioned ester in THF (50 mL) was added aqueous LiOH (1 M, 50 mL). The reaction mixture was stirred at room temperature for 2 h and was then washed with EtOAc (60 mL). The aqueous layer was acidified with 1 N HCl (65 mL) and extracted with EtOAc (100 mL). The organic layer was washed with brine (100 mL) whereby the aqueous layers were back-extracted with EtOAc (100 mL). The combined organic layers were dried over anhydrous Na_2SO_4, filtered, and concentrated *in vacuo*. To the residue was added CH_2Cl_2 (30 mL) when the desired product **S41** precipitated out and was collected by filtration (2.31 g, 63% over 3 steps).

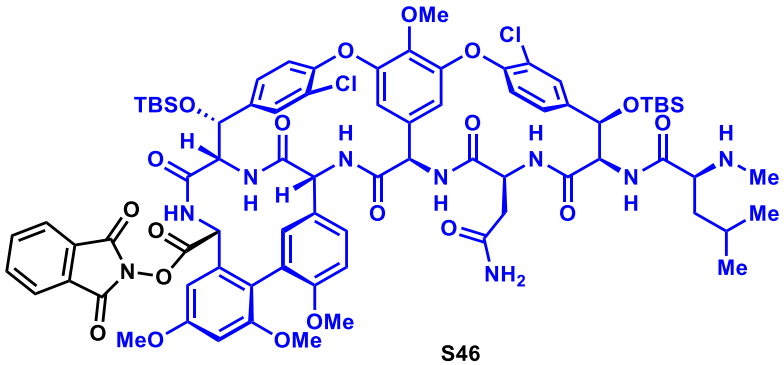
Compound S46



S46

To a suspension of **42** (45 mg, 0.029 mmol, 1.0 equiv.), *N*-hydroxyphthalimide (26 mg, 0.16 mmol, 5.5 equiv.), and *N*,*N*-dimethylpyridin-4-amine (0.4 mg, 0.0033 mmol, 0.11 equiv.) in CH_2Cl_2 (0.5 mL) was added *N*,*N*′-diisopropylcarbodiimide (25 µL, 0.16 mmol, 5.5 equiv.). The reaction mixture was stirred at room temperature for 1 h before AcOH (10 µL) was added. The resulting mixture was stirred for another 2 h and was subjected to flash column chromatography directly [silica gel, column: *d* 1.6 cm × *l* 7.5 cm, 3:2 EtOAc:hexanes (200 mL) to 1:19 MeOH:CH_2Cl_2 (120 mL)]. The combined fractions eluted with MeOH-CH_2Cl_2 were concentrated under reduced pressure, and the residue (31 mg) was used in next step without further purification.

Note:

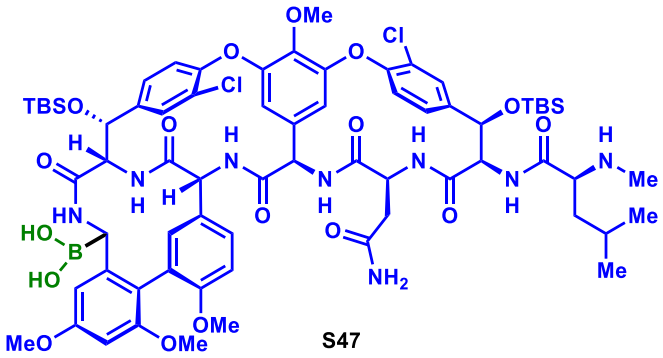
*(1) LC/MS indicated that the desired redox-active ester (**S46**) only eluted with MeOH/CH_2Cl_2. Nonpolar impurities, such as 1,3-diisopropylurea, were found to elute with EtOAc/hexanes.*

(2) Additional amounts of DMAP or longer reaction time have deleterious effects on

the reaction yield.

*(3) This redox-active ester (**S46**) was rather unstable and should be used in next step within 3 h after purification. Alternatively, it can be stored at –20 °C.*

Compound S47



S47

A screw-capped culture tube containing **S46** (31 mg), $MgBr_2$•OEt_2 powder (38 mg, 0.15 mmol) was evacuated and backfilled with argon for three times. Suspension C (0.4 mL, $NiCl_2$•$6H_2O$/di-*t*Bubipy in THF) was added next and the mixture was stirred vigorously at room temperature for 15 min (or sonicated until no granular $MgBr_2$•OEt_2 was observed). The resulting suspension was cooled to 0 °C, and the suspension of [B_2pin_2Me]Li in THF (0.55 mL) was added in one portion. After stirring for 1 h, the reaction mixture was diluted with CH_2Cl_2 (5 mL), filtered through a short pad of silica gel and celite, washed with 5% MeOH/CH_2Cl_2 (50 mL). The filtrate was concentrated under reduced pressure, and the residue was subjected to flash column chromatography directly [silica gel, column: *d* 1.6 cm × *l* 7.5 cm, 1:1 EtOAc:hexanes (200 mL) to 1:19 MeOH:CH_2Cl_2 (120 mL)]. The MeOH/CH_2Cl_2 elution was concentrated under reduced pressure, and the residue (16 mg) was used in next step without further purification.

Note:

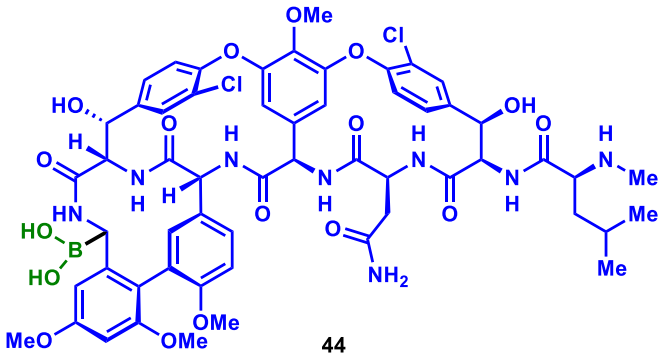
(1) The pinacol ester was found to hydrolyze during the reaction based on LC/MS analysis.

*(2) LC/MS indicated that **S47** only eluted with MeOH/CH_2Cl_2 based on LC/MS analysis.*

Nonpolar impurities, such as B_2pin_2, were found to elute with EtOAc/hexanes.

(3) Not all impurities can be removed through flash chromatography in this step; instead the unpure materials were carried forward to the next step.

Compound 44



44

To a solution of **S47** (16 mg) in CH_3CN (1.3 mL) was added a solution of tris(dimethylamino)sulfonium difluorotrimethylsilicate (TASF) in DMF (120 μL, 1.0 M). The mixture was stirred at room temperature for 1.5 h and was concentrated to a final volume of *ca.* 0.3 mL under reduced pressure. The residue was purified by preparative reverse-phase HPLC (20%–50% CH_3CN/H_2O over 30 min, both CH_3CN and H_2O containing 0.1% TFA) to afford **44** (4.1 mg, 11% over 3 steps) as a TFA salt.

Note: This compound was not stable in neat condition due to its propensity toward polymerization. Therefore, the purified compound was dissolved immediately. Solutions in MeOH were used for HRMS; solutions in MeOH-d_4 were used for for NMR study; solutions in DMSO were used for biological studies.

Experimental Procedure for Antibiotic Evaluation of 43, 44, Vancomycin and Vancomycin Aglycon.

Antibiotic susceptibilities were determined using the Clinical and Laboratory Standards Institute broth microdilution method (*63*). Briefly, antibiotics were prepared as 2-fold dilutions in 96-well plates containing cation-adjusted Mueller-Hinton broth (*S. aureus* strains) or brain-heart infusion broth (*Enterococcus* strains). Stock solutions of antibiotics were made in dimethyl sulfoxide (DMSO). Wells were inoculated from a fresh plate scrape diluted to a final concentration of 5×10^5 CFU/mL and incubated at 37 °C. Growth observed visually at 20 h. All MICs are an average of at least three independent determinations.

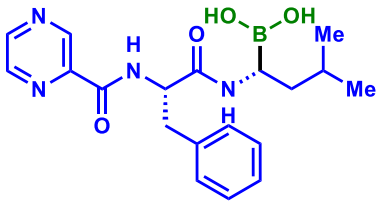
Compound 49



bortezomib (Velcade); **49**

(3-methyl-1-((*S*)-3-phenyl-2-(pyrazine-2-carboxamido)propanamido)butyl)boronic acid (49)

Bortezomib (**49**) was synthesized from **48** using the literature procedure (*19*) with slight modifications.

Boc deprotection: To a screw-capped culture tube charged with **48** (151 mg, 0.33 mmol) was added HCl in EtOAc (14 wt%) at 0 °C, and the reaction mixture was stirred at 0 °C for 3 h and room temperature for an additional 1 h. The reaction mixture was concentrated to dryness and the resulting solid was washed with hexanes. The desired product was afforded as a white solid and was used in next step without further purification.

Esterification: CH_2Cl_2 (1.2 mL, 0.5 M) was added to a screw-capped culture tube containing the hydrochloride salt obtained from the previous step. The mixture was cooled to 0 °C. Diisopropylethylamine (0.15 mL, 0.86 mmol) was added dropwise, and the reaction mixture was stirred for 5 min. 2-Pyrazine carboxylic acid (56 mg, 0.45 mmol) was then added to the solution in one portion. *o*-(Benzotriazol-1-yl)-*N*,*N*,*N*′,*N*′-tetramethyluronium tetrafluoroborate (TBTU, 118 mg, 0.37 mmol) was then added to the reaction mixture which was stirred at 0 °C for 2 h and room temperature for additional 1 h. The reaction mixture was then concentrated *in vacuo*. The crude residue was dissolved in EtOAc (10 mL) and transferred to a separatory funnel. The organic layer was washed with deionic H_2O (2 × 10 mL), 1% phosphoric acid (2 × 10 mL), 2% K_2CO_3 (2 × 10 mL), and brine (2 × 10 mL) successively. Each aqueous layer was back-extracted with EtOAc (2 × 10 mL). The combined organic layers were dried over anhydrous Na_2SO_4, filtered and concentrated *in vacuo*. The resulting pale yellow foam was carried on to the next step without further purification.

Boronate ester exchange: Pentane (0.8 mL) and MeOH (0.8 mL) were added to a screw-capped culture tube containing the pinacol boronate obtained from the previous step. 2-Methylpropaneboronic acid (125 mg, 1.2 mmol) was then added to the solution. 1 N aq. HCl (0.6mL) was added to the reaction mixture, and the resulting biphasic solution was stirred vigorously for 16 h. Stirring was then stopped and the biphasic mixture was allowed to separate. The aqueous layer was washed with pentane (2 × 10 mL) and was then concentrated *in vacuo*. The resulting film was partitioned between CH_2Cl_2 and 1 N aq. NaOH (10 mL). The aqueous layer was washed with CH_2Cl_2 (3 × 10 mL) and the organic phase was back-extracted with 1 N aq. NaOH (2 × 10 mL). 1 N aq. HCl was added to the combined aqueous layers until the pH = 6 when the desired product was extracted into the organic layer with CH_2Cl_2 (3 × 10 mL). The combined organic phase was dried over anhydrous Na_2SO_4, filtered, and concentrated *in vacuo*. The resulting residue was dissolved in EtOAc (2 mL), and the solution was subsequently concentrated

in vacuo. To the residue was then added hexanes (2 mL), and the suspension was concentrated *in vacuo* to afford the product **49** (64 mg, *d.r.* = 5.1 :1, 51% over 3 steps).

Elastase Inhibition Assay

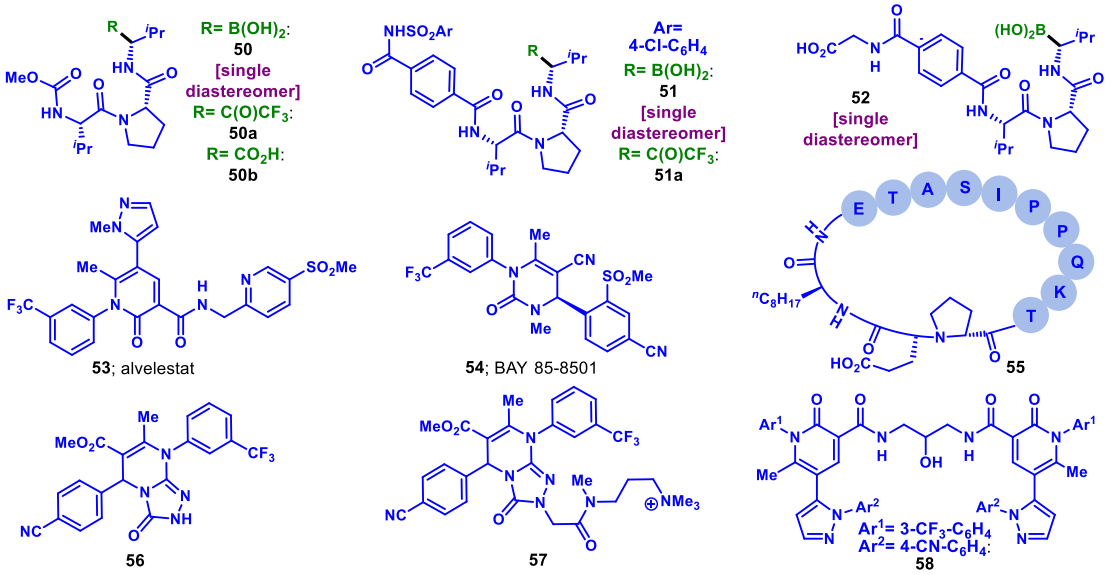

Figure S40. Strutures of selected elastase inhibitors.

Materials and methods:

Compounds **50**–**58**, **50a**, **50b**, and **51a** were subjected to this assay.

Serially diluted compounds in DMSO were dispensed into a 384-well black opaque plate by Echo dispenser. 0.1 μg/mL human neutrophil elastase (EPC, Catalog# SE563, Owensville, MS) or human sputum diluted with assay buffer (100 mM HEPES, 500 mM NaCl, 0.02% Tween 20) was added into the 384-well plate, and was incubated with different compounds at different concentrations for 30 minutes at room temperature. The final concentration of DMSO in the reaction was 0.1%. Elastase substrate MeOSuc-AAPV-AMC (Bachem, Catalog # I-1270, Torrance, CA) of 100 μM final concentration was then added into the reaction system just before enzyme kinetics were read on PheraSTAR plate reader at excitation of 380 nm and emission of 460 nm with a 3-minutes interval for 30 minutes in total. Slope of fluorescence intensity vs. time representing the V_{max} of enzyme activity was calculated with MARS software. %relative inhibition was calculated as:

$$\frac{Slope_{DMSO} - Slope_{inhibitor}}{Slope_{DMSO}} \times 100\%$$

IC_{50} was calculated based on the % relative inhibition curve using log(agonist) *vs.*

response (three parameters) method with Prism software. All experiments were performed in triplicate for at least three independent times. The IC_{50} results of all experiments are shown as the average of triplicates with error bar indicating standard deviation as indicated in individual figures. For compounds **51**, **52**, and **58**, the assay above was repeated with 2.5, 25, 50 and 100 μM of elastase substrate (MeOSuc-AAPV-AMC) and Ki/nM values were calculated based on these results using the mixed model (*68*).

Quantification of elastase concentration in human sputum:

Human sputum was purchased from Discovery Life Sciences (Los Osos, CA). Human sputum was diluted 1:10 in volume with assay buffer (100 mM HEPES, 500 mM NaCl, 0.02% Tween 20) followed by vigorous vortexing. The 1:10 diluted human sputum was further diluted into 1:30, 1:90, 1:270, 1:810, and 1:2430. The elastase concentration was determined by elastase inhibition assay as described above. Specifically, a series of standards of human neutrophil elastase (starting at 2 μg/mL and further diluted 1:2 in volume) were prepared in the assay buffer. The samples and standards were plated in a 384-well black solid bottom plate; the substrate MeOSuc-AAPV-AMC of 100 μM final concentration was then added into the reaction system just before enzyme kinetics were read on PheraSTAR plate reader as mentioned above. The slope of enzymatic kinetic reading was calculated by MARS software. The elastase levels of the human sputum were calculated based on the standard curve.

Time Dependence of Elastase Inhibition

Method:

The procedure for the elastase inhibition assay (Page S164-166) was followed with slight modifications. 0.1 μg/mL human neutrophil elastase was incubated with a range of concentrations of inhibitors for 5, 15, 30 and 60 minutes before substrate MeOSuc-AAPV-AMC of 100 μM final concentration was added. Enzyme kinetics were read on PheraSTAR plate reader and IC_{50} was calculated with the method described above.

Plasma Stability Assay

Materials:

1) Compounds **50**, **50a**, **51**, **51a** and **52** were tested. Propantheline was used as the reference compound in this assay; all stock solutions were stored at –40°C before use.

2) **Test system**: CD-1 Mouse Plasma from a minimum of 20 male individuals were obtained from BioreclamationIVT (Catalog #: MSEPLEDTA2-M; Batch #: MSE244515). EDTA-K2 was used as the anticoagulant.

Procedure:

The frozen plasma was thawed in a water bath at 37 °C prior to the experiments. The plasma was centrifuged at 4000 rpm for 5 min and the clots were removed if necessary. The pH was adjusted to 7.4 ± 0.1 as necessary. An intermediate solution (1 mM) was prepared and a 100 μM dosing solution was prepared by diluting 10 μL of the intermediate solution with 90 μL 45% MeOH/H_2O. Duplicate of test samples were made by mixing 98 μL of blank plasma with 2 μL of dosing solution (100 μM) to achieve the final concentration of 2 μM. Samples were incubated at 37 °C. At each time point (0, 10, 30, 60, and 120 min), 400 μL of stop solution (consisting of 200 ng/mL tolbutamide and 20 ng/mL buspirone in 50% MeOH/CH_3CN) was added to precipitate protein under thorough mixing. The sample plates were then centrifuged at 4,000 rpm for 10 min. An aliquot of supernatant (100 μL) was transferred from each well and mixed with 200 of μL ultrapure water. The samples were shaken at 800 rpm for about 10 min before LC-MS/MS analysis.

Data analysis: The % remaining of test compound after incubation in plasma was calculated using following equation:

$$\% \text{ Remaining} = 100 \times (P_{AR} \text{ at } T_n / P_{AR} \text{ at } T_0)$$

where P_{AR} is the peak area ratio of analyte versus internal standard (IS) and The appointed incubation time points are T_0 (0 min), T_n (n=0, 10, 30, 60, 120 min).

LC-MS/MS condition: Each compound was analyzed by LC/MS using an ACE 5-phenyl 50×2.1 mm column (Part No. ACE-125-0502) with 0.1% formic acid in water and 0.1% formic acid in acetonitrile as the mobile phases. Tobultamide was used as the internal standard. Data collected were processed by Analyst 1.6.2 software and MultiQuant 3.0.2 software.

Mouse Liver Microsomal Metabolic Stability Assay

Materials:

1) Compounds **50**, **50a**, **51**, **51a**, and **52** were tested in this assay. Testosterone, Dichlofenac, and Propafenone were used as control.

2) **Buffers:**

1. 100 mM potassium phosphate buffer, pH 7.4.
2. 10 mM $MgCl_2$

3) **Compound Dilution:**

Intermediate solution was prepared by diluting 5 μL of compound or control stock solution (10 mM in DMSO) with DMSO (45 μL) and 1:1 methanol/water (450 μL) (concentration=100 μM, 45% MeOH). Working solution was prepared by diluting 50 μL of the intermediate solution with 450 μL of 100 mM potassium phosphate buffer, pH=7.4 (centration= 10 μM, 4.5%MeOH).

4) **NADPH regenerating system** (final Isocitric dehydrogenase concentration = 1 unit/mL at incubation) comprised:

β-Nicotinamide adenine dinucleotide phosphate acquired from Sigma (Catalog # N0505), isocitric acid from Sigma (Cat. No. I1252) and isocitric dehydrogenase from Sigma (Catalog # I2002).

5) **Liver microsome solution** (final concentration of 0.5 mg protein/mL) was prepared using Mouse liver microsomes from Xenotech (Catalog # M1000, Lot # 1310028).

6) **Stop solution**: Cold acetonitrile containing 100 ng/mL Tolbutamide and 100 ng/mL Labetalol as internal standards (IS)

Procedure:

10 μL/well of compound working solution or control working solution was added to all plates (T0, T5, T10, T20, T30, T60, NCF60) except the matrix blank. 80 μL/well of microsome solution was added to every plate. The mixtures of microsome solution and compound were incubated at 37 °C for about 10 min. 10 μL/well of NADPH regenerating system (pre-warmed to 37 °C) was then added to every plate to start the reaction. The plates were incubated for the durations indicated (matrix blank: 1 h; T60: 1 h; T30: 31 min; T20: 40 min; T10 50min; T5: 55min). For NCF60 (abbreviation of no co-factor) no NADPH regenerating system was added, but was replaced by 10 μL/well of potassium phosphate buffer (100 mM, pH 7.4); the resulting mixture was incubated at 37 °C for 1 h.

The reactions were then terminated with the stop solution (cold at 4 °C) containing 100 ng/mL Tolbutamide and 100 ng/mL Labetalol (300 μL/well). The sampling plates were shaken for approximately 10 minutes, then were centrifuged at 4000 rpm for 20 min at 4 °C. While centrifuging, 8 new 96 well plates were loaded with 300 μL of HPLC grade water. 100 μL of supernatant was finally added to 300 μL of HPLC grade water and mixed for LC/MS/MS analysis.

Apricot pipetting robot was used for all additions, mixing, and transformations described above in 96-well plate format.

Data Analysis

The equation of first order kinetics was used to calculate $T_{1/2}$ and $Cl_{int(mic)}$:

$$C_t = C_o \bullet e^{-k_e \bullet t}$$

$$\text{when } C_t = \frac{1}{2} C_o,\ T_{1/2} = \frac{ln2}{k_e} = 0.693/k_e$$

$$CL_{int(mic)} = \frac{0.693}{in\ \ vitro\ \ T_{1/2}} \bullet \left(\frac{1}{\frac{mg}{mL}\ \ microsomal\ \ protein\ \ in\ \ reaction\ \ system} \right)$$

$$CL_{int(liver)} = CL_{int(mic)} \bullet \left(\frac{mg\ \ microsomes}{g\ \ liver} \right) \bullet \left(\frac{g\ \ liver}{Kg\ \ body\ \ weight} \right)$$

Notes: *1) * NCF: the abbreviation of no co-factor. No NADPH regenerating system was added into NCF samples (replaced by buffer) during the 60 min-incubation, if the NCF remaining is less than 60%, then Non-NADPH dependent occurs.*

2) R^2 is the correlation coefficient of the linear regression for the determination of kinetic constant.

3) $T_{1/2}$ is half-life and $CL_{int\ (mic)}$ is the intrinsic clearance.

4) $\frac{mg\ \ microsomes}{g\ \ liver} = 45mg/g$ for five species.

5) $\frac{g\ \ liver\ \ weight}{Kg\ \ body\ \ weight} = 88g/Kg$ for mouse.

6) Hepatic blood clearance (CLH) = $\frac{CLint(liver)\times\ Qh}{CLint(liver)+Qh}$

Hepatic extraction ratio (EH) = $\frac{CLH}{QH}=\frac{Clint(liver)}{Clint(liver)+Qh}$

Whereby Qh(mL/min/Kg liver） = 90.0 mL/min/Kg for mouse liver

***Caco-2* Permeability Assay**

Materials:

1) ***Caco-2* culture**: Caco-2 cells purchased from ATCC were seeded onto polyethylene membranes (PET) in 96-well BD Insert plates at 1 x 105 cells/ cm^2, and refreshed medium every 4~5 days until to the 21st to 28th day for confluent cell monolayer formation.

2) **Compound information**: compounds **51** and **51a** were subjected to the assay. Digoxin, fenoterol, and propranol were used as standards respectively.

Transport method:

The transport buffer used in the study was HBSS with 10 mM HEPES at pH 7.40±0.05. Compounds were tested at 2 μM bi-directionally in duplicates. Digoxin was tested at 10 μM bi-directionally in a duplicate, while fenoterol and propranolol were tested at 2 μM in A(apical) to B (basolateral) direction in duplicates. The final DMSO concentration was adjusted to less than 1%. The plate was incubated for 2 hours in a CO_2 incubator at 37±1°C, with 5% CO_2 at saturated humidity without shaking. All samples, after mixing with acetonitrile containing internal standard, were centrifuged at 4000 rpm for 20 min. Subsequently,100 μL supernatant solution was diluted with 100 μL distilled water for LC/MS/MS analysis. Concentrations of test and control compounds in starting solution, donor solution, and receiver solution were quantified by LC/MS/MS methodologies, using peak area ratio of analyte/internal standard. After transport assay, lucifer yellow rejection assay was applied to determine the *Caco*-2 cell monolayer integrity. All data presented herein have passed this test.

Data analysis: The apparent permeability coefficient Papp (cm/s) was calculated using the equation:

$$P_{app} = \left(\frac{dC_r}{dt}\right) \bullet V_r/(A \bullet C_0)$$

Where $\frac{dC_r}{dt}$ is the cumulative concentration of compound in the receiver chamber as a function of time (μM/s); V_r is the solution volume in the receiver chamber (0.075 mL on the apical side, 0.25 mL on the basolateral side); A is the surface area for the transport, *i.e.* 0.0804 cm^2 for the area of the monolayer; C_0 is the initial concentration in the donor chamber (μM).

The efflux ratio was calculated using the equation:

$$\text{Efflux ratio } = P_{app}(BA)/P_{app}(AB)$$

Percent recovery was calculated using the equation:

$$\%\ \ Recovery = 100\times[(V_r \bullet C_r) + (V_d \bullet C_d)]/(V_d \bullet C_0)$$

Where V_d is the volume in the donor chambers (0.075 mL on the apical side, 0.25 mL on the basolateral side); C_d and C_r are the final concentrations of transport compound in donor and receiver chambers, respectively.

LC/MS conditions: Each compound was analyzed by LC/MS using an ACE 5-phenyl 50×2.1 mm column (Part No. ACE-125-0502) with 0.1% formic acid in water and 0.1% formic acid in acetonitrile as the mobile phases. Tobultamide was used as the internal standard. Data collected were processed by Analyst 1.6.2 software and MultiQuant 3.0.2 software.

Table S19. Result of *Caco-2* permeability assay.

Compound ID	Mean P_{app} (10^{-6} cm/s)		Efflux Ratio	Mean Recovery %	
	A to B	B to A		A to B	B to A
Fenoterol	0.24	ND	–	93.38	ND
Propranolol	19.76	ND	–	69.25	ND
Digoxin	<0.02	8.50	>364.02	<91.21	100.33
51	<0.16	0.61	>3.91	<88.25	99.12
51a	<0.08	<0.12	NA	<74.15	<90.87

Note:

1) For digoxin and test compound, the signal responses in receiver samples were lower than the limit of quantification. For the convenience of calculating P_{app} values, 50 was used as the peak area of analyte in receiver samples instead.

2) The permeation was assessed over a 120-minute incubation at 37±1°C and 5% CO_2 with saturated humidity.
